## G-Range

G-Range is a global model that simulates generalized changes in rangelands through time, created with support from the International Livestock Research Institute. Spatial data and a set of parameters that control plant growth and other ecological attributes in landscape units combine with computer code to represent ecological process such as soil nutrient and water dynamics, vegetation growth, fire, and wild and domestic animal offtake. The model is spatial, with areas of the world divided into square cells. Those cells that are rangelands have ecosystem dynamics simulated. A graphical user interface allows users to explore model output.

The G-Range application captures main primary production and its dynamics. It is of moderate complexity, and of a nature that a user may learn its use in a week or less. A monthly time step is used to simulate herbaceous plants, shrubs, and trees, and those plant types can change in their

covers within each landscape cell through simulated time. The model represents all rangelands within a single computer process, which simplifies the logistics involved in analyses. Simulations may span a few to thousands of years. Detailed information about G-Range and the reason for its creation are described in Boone et al. (2011).

In August 2011, a beta version of G-Range was provided to collaborators. The beta version of G-Range that was distributed in a limited way included a parameter set that created draft responses from the model at 1 degree x 1 degree spatial resolution. Those draft responses were useful for demonstrating the architecture of the model, but had not been rigorously compared to observations. As part of this second effort, the values within that parameter set were edited based on information from the literature, published spatial surfaces, and our experience. Extensive sensitivity analyses were then conducted.

### **Baseline Simulation Methods**

To guide creation of a baseline simulation we required some data that would be deemed ‘truth.’ These data were used to compare to output from G-Range. The intent of these comparisons was not to yield a final parameter set that would represent well all areas within 15 biomes forever after. Instead, it was to allow adjustment of parameters to change G-Range output from essentially uncontrolled to something more in agreement with reality. In-so-far as that was the goal, only cursory effort was put into determining the validity of what is here deemed ‘truth;’ we proceeded knowing that comparing results to published or vetted data would be helpful. That included for simulated output from the Century model. That model has been vetted many times and gridded summaries of simulations are suitable for comparison with G-Range output. In other words, given the unlimited range that G-Range output could take, it would be reassuring if output emulated results from the Century model.

We adopted a spatially explicit means of comparing global responses from G-Range to various responses. Simulations started in 1957 and continued for 50 years, to 2006. Where year-specific data were available, data from 2006 were used. For some spatial data, specific years were not available, and so recent general responses were used. In this baseline simulation, fire was not incorporated and fertilization has not been included.

We began with a list of the 100+ responses from G-Range, and then selected from those the types of responses that would be most helpful in comparisons. We then compiled from existing Century simulations or materials from web sites spatial data at 0.5 degree x 0.5 degree resolution, the resolution used in this report. Cross-tabulating those lists yielded a set of surfaces used in assessment. The 11 surfaces that were selected are show in Table 1.

---

---

**Table 1.** The global surface data used in comparisons with G-Range output during baseline model fitting and sensitivity analyses.

1. **Potential evapotranspiration:** The values were compiled from Century output from simulations at 0.5 degree x 0.5 degree resolution (Conant et al., in prep.).
  2. **Soil surface temperature:** Soil temperature values were compiled from Century output from simulations at 0.5 degree x 0.5 degree resolution (Conant et al., in prep.).
  3. **Snow-water equivalent:** Gridded snow water equivalent estimates created from satellite imagery, with values from 2006 used (Armstrong et al. 2005). These data are at 25 km x 25 km resolution, with values averaged here to yield landscape cell values.
  4. **Annual evapotranspiration:** Summed from a collection of grids produced at 8 km x 8 km resolution showing continuous satellite-derived global monthly land surface evapotranspiration for 2006 (Zhang et al. 2010). The surfaces were generalized to 0.5 degree x 0.5 degree resolution by averaging pixel values. Values in mm/yr were converted to cm/yr prior to use.
  5. **Plant-available soil water:** Available water was summarized from 0.5 degree x 0.5 degree resolution simulations from the Century model (Conant et al., in prep.).
  6. **Decomposition coefficients:** Decomposition coefficients are corrections applied to rates of decomposition. Here, values were taken from set of modeling results from compiled 0.5 degree x 0.5 degree simulations from the Century model (Conant et al., in prep.).
  7. **Soil organic carbon:** Total soil organic carbon was taken from compiled simulations at 0.5 degree x 0.5 degree in the Century model (Conant et al., in prep.).
  8. **Carbon to nitrogen ratio:** From 0.5 degree x 0.5 degree estimates of carbon to nitrogen ratios within the ISRIC – World Soil Information database (Batjes 2002).
  9. **Live carbon density:** These data were calculate by summing above and below ground live carbon densities from the New IPCC Tier-1 Global Biomass Carbon Map of the Year 2000 (Ruesch et al. 2008). The original map was at approximately 1 km x 1 km resolution, and values were averaged to yield the estimates used. Those estimates were converted from tons carbon per ha to g/m<sup>2</sup>.
  10. **Annual net primary production:** Summed across months for net primary productivity within a 0.5 degree x 0.5 degree suite of Century simulations compiled into global surfaces (Conant et al., in prep).
  11. **Leaf area index:** Data were summed from 1998 estimates of total leaf area index at 0.5 degree x 0.5 degree resolution from the ISLSCP II FASIR-Adjusted NDVI Biophysical Parameter Fields project (Sietse 2010).

-

A significant product from this work is a program called FIT.AML which works in ESRI's (Redlands, CA) Arc Workstation software (listed in Appendix B). The program was critical in supporting the hundreds of simulations that have been made, each creating goodness-of-fit reports. For a given analysis, first, parameter values were edited by hand. Then FIT.AML was run, and it in turn ran the G-Range model. Then the 11 parameters listed were processed in turn. For each, an extraction tool described in Boone et al. (2011) was run which drew from the binary files produced by G-Range the data needed, for years 2004 to 2006 – 2006 was used in comparison to spatial surfaces. The extraction program created a series of layers in ESRI ASCII grid format. These were then converted to grids, the native format ArcGIS uses to store raster data, and then processed to remove values representing null values. Next, any summary statistics were done, such as averaging or summing monthly values as appropriate. Analyses on a given parameter were completed by subtracting the observed (i.e., the surfaces in Table 1) values from simulated values, yielding a deviation from observed for each pixel. Those values were then averaged for each biome. The program then created a report summarizing three types of data, the deviation from observed values, the observed values themselves, and the counts of cells used to derive the values reported. The last two entries are the same for all reports, but having them included in each report provided context.

The FIT.AML program then calls a tool that exports the facet covers for herbs, shrubs, and trees, plus bare ground cover, for the entire history of the simulation, 1957 to 2006. These are summarized every five years, from 1960 to 2005. The system then combines the results for herbs, shrubs, trees, and bare ground in a single file for each fifth year summarized. The program ends by creating a report in CSV format that summarizes changes in facet cover every five years for each of the 15 biomes assessed.

We did not make use of what is termed a 'spin-up' period when creating the baseline simulation or in sensitivity analyses, which has implications for the degree to which agreement could be reached between G-Range output and the surfaces we used in comparison, especially in regard to soil carbon and carbon to nitrogen ratio. Spin-up periods are used to allow simulation states to reach equilibrium. For example, in Century simulations, users often run the model for 2000 years to allow soil carbon pools to reach equilibrium, and save the state of the model. When using the application in analyses, analysts use the files that were generated from the model spin-up as starting points. Here, we did not want results dependent (partially) on the parameters used during a model spin-up period, and running the model for long time series in each simulation was not practical, and so a spin-up period was not used.

### **Baseline Simulation Results**

More than 120 simulations were conducted while parameters were adjusted and the fit of the model output was improved. During that effort we began to learn about the ways in which

parameters of G-Range influence model output. Most often responses were in the direction expected based on the processes the parameter informs, but sometimes the results were surprising. A subset of those surprises led to modify the G-Range code (with comments in the code tracking changes made). Ultimately, modifications seemed to be no longer improving the fit of the model, and the parameter set was judged suitable for the sensitivity analyses reported below. We stress that that parameter set is *not* intended to be a final parameter set to be released with G-Range. Rather, it brought essentially uncontrolled responses into some agreement with vetted global surfaces, and provided a baseline for the sensitivity analyses.

Table 2 shows the average responses for the 15 biomes represented in the initial G-Range application. Three sets of values are given, the deviation in the simulated results from the observed values, the observed values themselves, and a count of the number of landscape cells included in each biome that was treated as rangelands and simulated. The deviations should be interpreted in comparison to the magnitudes of the observed values. Biome 6, “Boreal evergreen forest or woodland” had insufficient rangeland cells to yield reliable results, and will not be addressed further.

Table 3 provides the average facet covers every five years (plus the initial 1957 values) for the 15 biomes. Included is bare ground cover, which is 1 minus the sum of the remaining facets. The goal for parameterizing of information in Table 3 was to generate stable facet covers through time.

**Table 2.** Baseline results for selected responses at the conclusion of a 50-year simulation. Three sets of values are provided, a) deviations in G-Range output from observations as recorded in spatial datasets for 2006, b) the observed values from the spatial datasets, and c) the numbers of 0.5 degree x 0.5 degree cells from which the statistics in 'a' and 'b' were calculated. Landscape unit identifiers include: 1 – Tropical evergreen forest or woodland; 2 – Tropical deciduous forest or woodland; 3 – Temperate broadleaf evergreen forest or woodland; 4 – Temperate needleleaf evergreen forest or woodland; 5 – Temperate deciduous forest or woodland; 6 – Boreal evergreen forest or woodland (which has insufficient cells in our analyses to yield reliable results); 7 – Boreal deciduous forest or woodland; 8 – Evergreen and deciduous mixed forest or woodland; 9 – Savanna; 10 – Grassland or steppe; 11 – Dense shrubland; 12 – Open shrubland; 13 – Tundra; 14 – Desert; 15 – Polar desert, rock, or ice. Variables used include: Soil temp. – Soil temperature; ET – Annual evapotranspiration; PET – Potential evapotranspiration; Plant H<sub>2</sub>O – Plant-available soil water; Decomp. coeff. – Decomposition coefficients; SOC – Soil organic carbon; C:N – Carbon to nitrogen ratio; Carbon dense. – Live carbon density; ANPP – Annual net primary productivity; LAI – Leaf area index.

Deviations shown in Table 2a are instructive on several levels. Two of the metrics we compared to we had suspected were not influenced by G-Range parameters (confirmed during sensitivity analyses), snow water-equivalent and potential evapotranspiration. The deviations in those metrics seen in Table 2a could never be influenced by changes made to parameters. The differences seen in those metrics are due to some combination of errors in the observed surfaces, incomplete descriptions of the processes, coding errors, or generalizations and errors in the input surfaces. Coding these processes is straightforward and their mathematical descriptions are well established. We suspect that the majority of deviations from the observed values are due to the generalized nature of CRU data (CRU 2008). Potential evapotranspiration was generally underestimated by perhaps 10%, except in polar biomes, where potential evapotranspiration was overestimated. Snow water-equivalent estimates were variable. Again, polar biomes were poorly estimated, and (for several metrics) were poorly estimated for biome 7, boreal deciduous forest or woodland.

Other metrics were influenced by changes in G-Range parameters in-so-far as vegetation cover or litter altered their values, such as soil temperature, annual evapotranspiration, plant-available soil water, and decomposition coefficients. Annual evapotranspiration was underestimated, and plant-available water was greatly overestimated, sufficient to require a review of the coding of G-Range. Decomposition coefficients were overestimated.

More parameters were available to control the values of soil organic carbon, carbon to nitrogen ratio, live carbon density, net primary productivity, and leaf area index. Live carbon density, annual net primary productivity, and leaf area indices were represented reasonably, but with some biomes represented less well. Soil organic carbon was sometimes represented quite well, but in polar biomes and in boreal deciduous forest or woodland estimates were too high, sometimes greatly overestimated.

Facet covers (Table 3) were relatively stable, as desired. Controls on plant establishment and whole plant death were sufficient to allow facet covers to be adjusted well. The lack of a spin-up period is evident, in that some facet covers vary from their base values in initial years prior to reaching some equilibrium.

### **Sensitivity Analysis Methods**

We conducted what is termed a local sensitivity analysis, where the influence of changing a single parameter was assessed, all else being unchanged. This contrasts with a global sensitivity analysis, where the sensitivity of a simulation to ambiguity in many inputs is assessed simultaneously. Such an analysis is helpful, but beyond the scope of this effort. Another simplification that was made was to not conduct sensitivity analyses on the 11 parameters that

influence fire (plus fire would have had to have been parameterized), or the five parameters that allow fertilization (plus its parameterization).

G-Range outputs may be reported directly in sensitivity analyses (i.e., the equivalent of Tables 2 and 3 for every simulation), but the deviations seen in outputs versus the observed surfaces would make that confusing. Instead, the baseline simulation (Tables 2, 3) was the datum to which sensitivity results from G-Range simulations were compared. Deviations from the values in those tables were of interest. Seven sensitivity values were tested for each parameter, with one of those values typically being that used in the baseline simulation. The range of values tested was suggested by variability in values between biomes, by practical limits, or by our knowledge of reasonable ranges for parameters.

A version of the FIT.AML was modified to support sensitivity analyses, and a brief program was prepared to run the seven simulations in sequence. A main change made was to reporting, in that G-Range output included the subtraction of results from the baseline simulation. A suite of seven parameter files was edited by hand to represent a single sensitivity analysis. Each set of seven simulations required about 8 hours to complete, and 94 such analyses were used to characterize the sensitivity of 56 variables. The difference in counts is due to their being families of values given for some parameters. For example, *leaf\_death\_rate* provides three values, one for herbs, one for shrubs, and one for trees. Each was assessed separately. Results from two variables are not available due to technical difficulties.

To constrain the length of this report, we limited the summary for each sensitivity analysis to one page. Three graphs are provided, often one of a selected facet cover and two chosen from the 11 candidate physical or biochemical responses assessed. No spatial responses are presented, as these assessments are at the biome scale; averages of rangeland cells within biomes were what was assessed. In each page, the purpose of the parameter was described. The means that were used to assign baseline values was cited. The values used in sensitivity analyses were reported. In that table and in the figures, for simplicity, the simulations are referred to by the numbers 1 through 7. Readers may refer to the table of sensitivity analyses to see the values referred to by the numbers. Results are interpreted, and then brief conclusions are drawn.

## **Sensitivity Analysis Results**

# 1. Precipitation threshold

**Purpose:** The variable `prcp_threshold` describes the amount of precipitation, in cm, that is required for their to be runoff. Runoff is lost to the system and stored as an accumulate which is output.

**Basis for assignment:** The variable is PRECRO in Century 4.5, and the value for landscape units was assigned based on the example files released with that software.

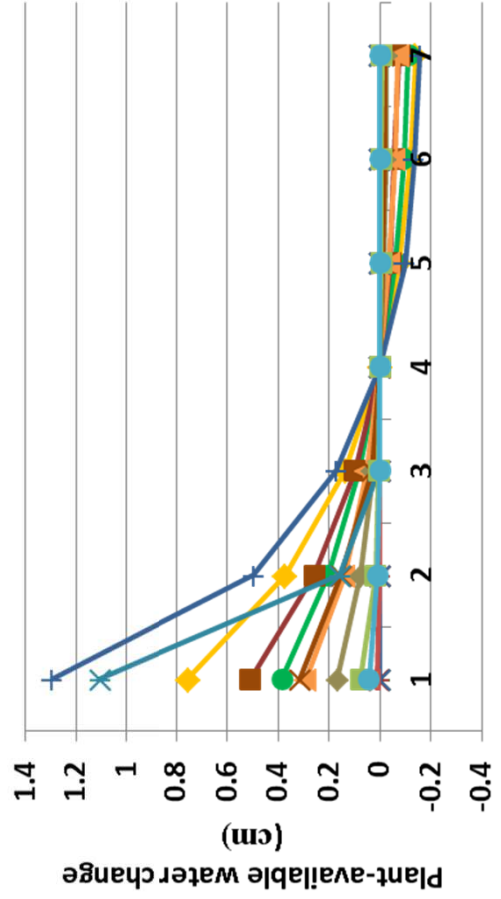

## Baseline values:

8.00 cm (for all landscape units)

## Sensitivity values:

- 1 – 2.00
- 2 – 4.00
- 3 – 6.00
- 4 – 8.00
- 5 – 10.00
- 6 – 12.00
- 7 – 14.00

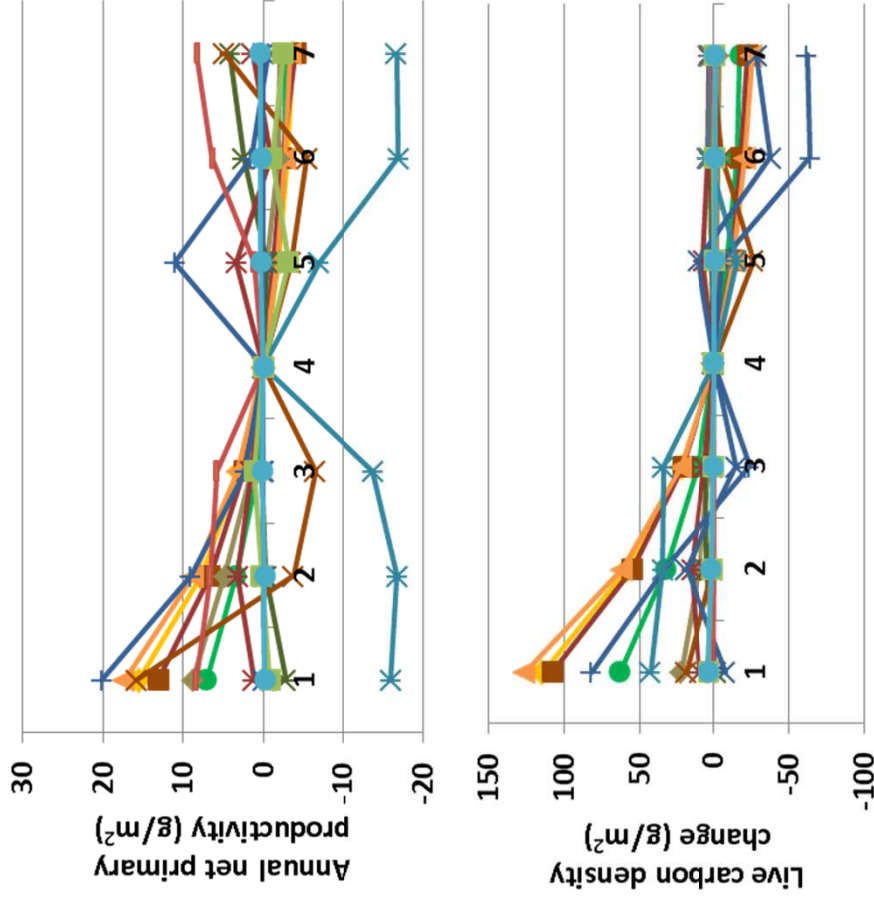

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

## Interpretation:

Snow water equivalent and potential evapotranspiration did not change. Soil temperature changed a fraction of degree. Actual evaporation increased up to 15 cm in some landscape units with precipitation threshold at 2.00c cm. Soil organic carbon increased to up to 170 g m<sup>-2</sup> in tropical deciduous forest, but otherwise changed less than 100 g m<sup>-2</sup>. Net primary productivity changed up to 20 g m<sup>-2</sup> (top) and live carbon density up to 125 g m<sup>-2</sup> (above). Cover of herbs, shrubs, and trees changed 2% or less (left).

**Conclusion:** The parameter captures an important process and has mostly moderate influences on assessed outcomes. The parameter should be retained.

## 2. Precipitation threshold fraction

**Purpose:** The variable `prcp_threshold_fraction` describes the amount of precipitation in each month that is lost to runoff. Precipitation on the soil is reduced by the precipitation threshold, then multiplied by this fraction to determine runoff.

**Basis for assignment:** The variable is FRACRO in Century 4.5, and the value for landscape units was assigned based on the example files released with that software. Two entries were reduced in fitting.

### Baseline values:

0.02 (for units 1-2), 0.15 (for units 3-15)

### Sensitivity values:

- 1 – 0.00
- 2 – 0.05
- 3 – 0.10
- 4 – 0.15
- 5 – 0.20
- 6 – 0.25
- 7 – 0.30

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Snow water equivalent and potential evapotranspiration did not change. Soil temperature changed a fraction of degree. Actual evaporation increased up to 4 cm in some landscape units (left). Soil organic carbon decreased to up to 140 g/m<sup>2</sup> in, but some units increased less than 100 g/m<sup>2</sup>. Live carbon density (above) and net primary production (top) changed modestly. Cover of herbs, shrubs, and trees changed by 2% or less in simulations, except for a 6.5% decline in herbaceous cover and increase in bare ground for tropical broadleaf evergreen forest.

**Conclusion:** The parameter captures an important process and has mostly moderate influences on assessed outcomes.

### 3. Base flow fraction

**Purpose:** The variable base\_flow captures the fraction of soil water in the last layer of soil that is lost to base flow. The parameter influences mineral leaching from soils.

**Basis for assignment:** The variable is BASEF in Century 4.5, and the value for landscape units was assigned based on the example files released with that software. Examples released with that model were matched with landscape units.

**Baseline values:**

- 0.20 (for units 1-2, 10, 11)
- 0.30 (for units 3-9, 12)
- 0.00 (for units 13-15)

**Sensitivity values:**

- 1 – 0.000
- 2 – 0.075
- 3 – 0.150
- 4 – 0.225
- 5 – 0.300
- 6 – 0.375
- 7 – 0.450

**Interpretation:** Over the range of values used in sensitivity analyses, base flow fraction had no effect on any output metric summarized. This is the case for biogeochemical and production responses, and changes in facet covers as well.

**Conclusion:** A thorough review of the G-Range computer code is called for to ensure that the parameter is captured as appropriate. If shown to be correct, the parameter may be considered for removal.

## 4. Soil transpiration fraction

**Purpose:** The variable soil\_transpiration\_fraction describes the maximum fraction of water that may be transpired from each of the four soil layers. The value provides a cap on transpiration from a given layer.

**Basis for assignment:** The variable is AWTL in Century 4.5, and the value for landscape units was assigned based on the example files released with that software. Values were assigned the same for all landscape units based on those examples.

### Baseline values:

0.8, 0.6, 0.4, 0.2

### Sensitivity values:

- 1 – 0.50, 0.30, 0.10, 0.05
- 2 – 0.60, 0.40, 0.20, 0.10
- 3 – 0.70, 0.50, 0.30, 0.15
- 4 – 0.80, 0.60, 0.40, 0.20
- 5 – 0.90, 0.70, 0.50, 0.25
- 6 – 0.99, 0.80, 0.60, 0.30
- 7 – 0.99, 0.90, 0.70, 0.35

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes associated with soil transpiration fraction values were modest. Potential evapotranspiration and snow water equivalent did not change. Actual evapotranspiration changed < 2 cm, and soil temperature varied < 0.02 degrees. Soil organic matter changed up to 170 g m<sup>-2</sup> (left), and carbon to nitrogen ratio by 0.31. Trivial changes in facet cover occurred in the sensitivity analysis, with only tropical broadleaf evergreen forest showing a decline of 3%, and the rest < 2% in herbaceous cover.

**Conclusion:** The limit on soil transpiration fraction appears helpful, but does not alter outputs a great deal in the current application. The parameter may be retained for flexibility.

## 5. Initial soil carbon to nitrogen ratio

**Purpose:** The variable `init_soil_c_n_ratio` describes the soil carbon to nitrogen ratio that is used in initializing the model. The value initializes both a surface and subsoil layer, and nitrogen in intermediate and passive pools.

**Basis for assignment:** The variables for landscape units were initialized based on a published values in Potter et al. (Tellus 49B, 1-17; 1997).

### Baseline values:

Various values for the 15 landscape units, from 10.9 to 13.8

### Sensitivity values:

- 1 – 9.0
- 2 – 10.0
- 3 – 11.0
- 4 – 12.0
- 5 – 13.0
- 6 – 14.0
- 7 – 15.0

**Interpretation:** Decomposition coefficients (in addition to snow water equivalent and potential evapotranspiration) did not change. Initial soil carbon to nitrogen ratios appear to persist after 50 years of simulation (above). Annual net primary production changed < 25 g m<sup>-2</sup>. Live carbon density (above) changed up to 40 g m<sup>-2</sup>. Soil organic carbon changed up to 97 g m<sup>-2</sup> (left). Shrub and tree facets changes less than 1% in analyses. The herb facet increased up to 3.5%, and decreased < 2%, except for tropical broadleaf evergreen forest, which declined 5% in high C to N ratios.

**Conclusion:** Estimates for the parameter are readily available and capture an important trait. The parameter should be retained.

## 6. Initial lignin nitrogen ratio

**Purpose:** The variable `init_lignin_n_ratio` describes the lignin to nitrogen ratio used to initialize the model.

**Basis for assignment:** The variables for landscape units were initialized based on a published values in Potter et al. (Tellus 49B, 1-17; 1997).

### Baseline values:

Various values for the 15 landscape units, from 145 to 1100, but excluding types 14 and 15 (tundra and polar), the values are below 300.

### Sensitivity values:

- 1 – 100
  - 2 – 150
  - 3 – 200
  - 4 – 250
  - 5 – 300
  - 6 – 350
  - 7 – 400
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. deciduous forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** No changes in biogeochemistry, plant production, or facet cover were observed in sensitivity analyses. Initial lignin nitrogen ratio is used to calculate a fraction of metabolizable materials, but it not used in further calculations.

**Conclusion:** A review of G-Range computer code is called for, but the parameter appears to be used to calculate a fraction of metabolizable material, but not used thereafter. The code requires correction or the parameter may be removed.

## 7a. Initial tree carbon, live parts

**Purpose:** The variable tree\_carbon includes a live and dead set of values for leaves, fine roots, fine branches, coarse branches, and coarse roots. The values initialize carbon densities ( $\text{g m}^{-2}$ ) in the live plant parts.

**Basis for assignment:** The parameters were based on RLVGIS, RLVGIS, etc. in Century 4.5. These were similar across example land cover types, and set to a single suite of values in G-Range landscape units.

### Baseline values:

1200, 500, 800, 3500, 1200 (for all units)

### Sensitivity values:

- 1 – 900, 200, 500, 3200, 900
- 2 – 1000, 300, 600, 3300, 1000
- 3 – 1100, 400, 700, 3400, 1100
- 4 – 1200, 500, 800, 3500, 1200
- 5 – 1300, 600, 900, 3600, 1300
- 6 – 1400, 700, 1000, 3700, 1400
- 7 – 1500, 800, 1100, 3800, 1500

**Interpretation:** Initial carbon densities in live tree parts led to differences in carbon concentrations. Live carbon density changed up to  $500 \text{ g m}^{-2}$  in each direction (above). Carbon to nitrogen ratio changed less than 0.5 for plant types, most less than 0.1. Leaf area index changed up to 0.048 (top). Changes not shown tended to be minor (e.g.,  $< 0.1$  degree change in soil temperature). Herb facet cover changed 3% or less under different carbon concentrations in trees, with the values highest at lower C values.

**Conclusion:** An ability to initialize carbon density in tree parts is helpful, and has modest effects on simulation outcomes. The parameter group should be retained.

## 7b. Initial tree carbon, dead parts

**Purpose:** The variable tree\_carbon includes a live and dead set of values for leaves, fine roots, fine branches, coarse branches, and coarse roots. The values initialize carbon densities ( $\text{g m}^{-2}$ ) in the dead plant parts.

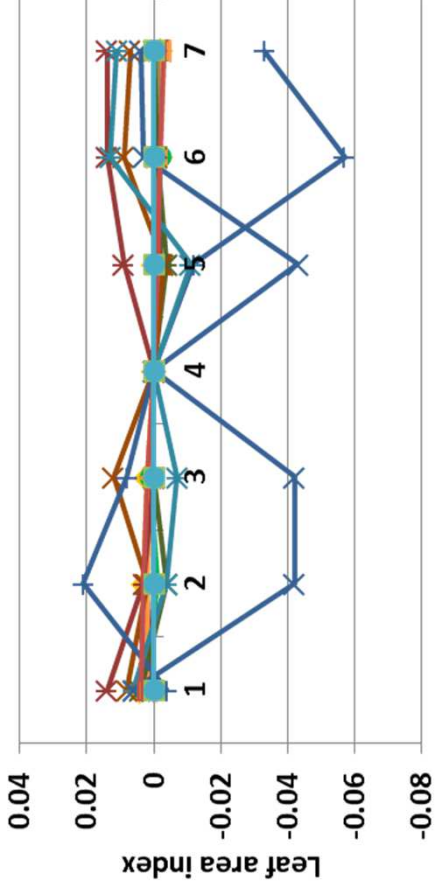

**Basis for assignment:** The parameters were based on RLVGIS, RLCWIS, etc. in Century 4.5. These were similar across example land cover types, and set to a single suite of values in G-Range landscape units.

### Baseline values:

100, 100, 300, 200, 300 (for all units)

### Sensitivity values:

- 1 – 55, 55, 255, 155, 255
- 2 – 70, 70, 270, 170, 270
- 3 – 85, 85, 285, 185, 285
- 4 – 100, 100, 300, 200, 300
- 5 – 115, 115, 315, 215, 315
- 6 – 130, 130, 330, 230, 330
- 7 – 145, 145, 345, 245, 345

**Interpretation:** Initial carbon densities in dead tree parts affect carbon concentrations after 50 years of simulation. Leaf area index showed small changes (top). Decomposition coefficients, soil temperature, and C to N ratio changed little. Live carbon density increased by  $250 \text{ g m}^{-2}$  at the lowest dead plant part carbon densities, to  $-200 \text{ g m}^{-2}$  at the highest dead plant part carbon densities. Herb facet cover changed 3% or less under different carbon concentrations, with the values highest at lower C values.

**Conclusion:** An ability to initialize carbon density in tree parts is helpful, and has modest effects on simulation outcomes. The parameter group should be retained.

## 8a. Initial shrub carbon, live parts

**Purpose:** The variable shrub\_carbon includes a live and dead set of values for leaves, fine roots, fine branches, coarse branches, and coarse roots. The values initialize carbon densities ( $\text{g m}^{-2}$ ) in the live plant parts.

**Basis for assignment:** The parameters were based on RLVGIS, RLWCIS, etc. in Century 4.5. These were similar across example land cover types, and set to a single suite of values in G-Range landscape units.

### Baseline values:

300, 150, 200, 800, 300 (for all units)

### Sensitivity values:

- 1 – 180, 30, 80, 680, 180
- 2 – 220, 70, 120, 720, 220
- 3 – 260, 110, 160, 760, 260
- 4 – 300, 150, 200, 800, 300
- 5 – 340, 190, 240, 840, 340
- 6 – 380, 230, 280, 880, 380
- 7 – 420, 270, 320, 920, 420

**Interpretation:** Initial carbon densities in live shrub parts led to differences in carbon concentrations after 50 years of simulation. Leaf area index changed a small amount (top), as did soil carbon (left). Live carbon density declined up to  $800 \text{ g m}^{-2}$  in forest units,  $400 \text{ g m}^{-2}$  in savanna, when carbon densities were low. When carbon densities were high, live carbon density increased up to  $500 \text{ g m}^{-2}$ . Shrub and tree facets changed less than 0.5%, and the herb facet changes 3.5% or less, with non-forest types changing 1.5% or less.

**Conclusion:** An ability to initialize carbon density in shrub parts is helpful, and has modest effects on simulation outcomes. The parameter group should be retained.

## 8b. Initial shrub carbon, dead parts

**Purpose:** The variable shrub\_carbon includes a live and dead set of values for leaves, fine roots, fine branches, coarse branches, and coarse roots. The values initialize carbon densities ( $\text{g m}^{-2}$ ) in the dead plant parts.

**Basis for assignment:** The parameters were based on RLVGIS, RLVGIS, etc. in Century 4.5. These were similar across example land cover types, and set to a single suite of values in G-Range landscape units.

### Baseline values:

40, 40, 80, 60, 80 (for all units)

### Sensitivity values:

1 – 10, 10, 50, 30, 50  
 2 – 20, 20, 60, 40, 60  
 3 – 30, 30, 70, 50, 70  
 4 – 40, 40, 80, 60, 80  
 5 – 50, 50, 90, 70, 90  
 6 – 60, 60, 100, 80, 100  
 7 – 70, 70, 110, 90, 110

**Interpretation:** Initial carbon densities in dead shrub parts do influence carbon densities later in simulations (above). Annual evapotranspiration changed by up to 1.3 cm for deciduous forest landscape units. Soil temperature changed by up to 0.04 degrees C. Plant-available water changed < 0.04 cm, with the grassland type showing the largest change. Soil organic carbon changed up to 40 g m<sup>-2</sup>, except for boreal deciduous forest. Shrub and tree facet covers essentially did not change. Herb cover changed up to 6% (left).

**Conclusion:** An ability to initialize carbon density in shrub parts is helpful, and has modest effects on simulation outcomes. The parameter group should be retained.

## 9. Plant dimension

**Purpose:** The variable plant\_dimension describes a single dimension of the area occupied by a plant root base. Three values are provided, one each for herbs, shrubs, and trees. Values are in meters.

**Basis for assignment:** These values were inferred.

**Baseline values:**

0.5, 2.0, 8.0 (for all units)

**Sensitivity values:**

- 1 - 0.2, 1.4, 5.0
- 2 - 0.3, 1.6, 6.0
- 3 - 0.4, 1.8, 7.0
- 4 - 0.5, 2.0, 8.0
- 5 - 0.6, 2.2, 9.0
- 6 - 0.7, 2.4, 10.0
- 7 - 0.8, 2.6, 11.0

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Herbaceous facet cover changed up to 4%. The logic of G-Range suggests that this is due to rounding error, in the sense that plant packing within the simulated 1 km<sup>2</sup> area was more complete when plants were small. Shrub and tree covers did not change. All biogeochemical and plant production responses were either no changes, or small responses associated with the changes in herbaceous facet cover. For example, soil organic carbon (above) changed less than 30 g m<sup>-2</sup>.

**Conclusion:** These values may be entered into G-Range directly (i.e., hard wired) and removed from the parameter set.

## 10a. Temperature production - Temperatures

**Purpose:** The variable temperature\_production describes the effect of temperature on plant production. There are two pieces, two parameters providing optimum and maximum temperatures, and two parameters describing the shape of the response curve. Here only temperature values are adjusted.

**Basis for assignment:** These values are variable PPDF in Century. Values distributed with that model for example biomes were used to initialize G-Range biomes.

### Baseline values:

- 30., 45., 1.0, 2.5 (units 1-2, 8-10, 14)
- 15., 32., 1.0, 3.5 (3-5, 7, 15)
- 19., 35., 1.0, 3.5 (6), 18., 35., 1.2, 3.0 (11, 12)

### Sensitivity values:

- 1 - 8., 24.
- 2 - 12., 28.
- 3 - 16., 32.
- 4 - 20., 36.
- 5 - 24., 40.
- 6 - 28., 44.
- 7 - 32., 48.

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in the temperatures associated with optimum and maximum production led to very large changes in outputs. Soil temperature declined up to 9 degrees C under low temperatures. Plant-available water declined more than 3 cm. Decomposition coefficients declined by 0.2. Soil organic carbon changed markedly (above). In general, these changes are associated with large changes in production (top). Facet covers all changed markedly as well, leading to change in bare ground (left).

**Conclusion:** These parameters are important in describing the process-based responses of plants, and apparently must be defined well to yield reasonable outputs. The parameters should be retained.

## 10b. Temperature production – Curve shapes

**Purpose:** The variable temperature\_production describes the effect of temperature on plant production. There are two pieces, two parameters providing optimum and maximum temperatures, and two parameters describing the shape of the response curve. Here only curve shapes are adjusted.

**Basis for assignment:** These values are variable PPDF in Century. Values distributed with that model for example biomes were used to initialize G-Range biomes.

### Baseline values:

- 30., 45., 1.0, 2.5 (units 1-2, 8-10, 14)
- 15., 32., 1.0, 3.5 (3-5, 7, 15)
- 19., 35., 1.0, 3.5 (6), 18., 35., 1.2, 3.0 (11, 12)

### Sensitivity values:

- 1 – 0.7, 2.25
- 2 – 0.8, 2.50
- 3 – 0.9, 2.75
- 4 – 1.0, 3.00
- 5 – 1.1, 3.25
- 6 – 1.2, 3.50
- 7 – 1.3, 3.75

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in the curves defining production responses to different temperatures led to very large changes in some outputs. Plant-available water declined more than 2 cm. Decomposition coefficients and C:N ratio showed modest responses (e.g., 0.7 change in C:N ratio). Carbon density changed markedly, up to 1600 g m<sup>-2</sup> increases in tropical forest types for sensitivity test 7 (above). Primary production did not change a great deal, up to 150 g m<sup>-2</sup>. Herbaceous facet cover changed (left), but less so for other facets

**Conclusion:** These parameters are important in describing the process-based responses of plants, and apparently must be defined well to yield reasonable outputs. The parameters should be retained.

## 11. Standing dead production halved

**Purpose:** The variable standing\_dead\_production\_halved captures a reduction in production based on structural material that causes physical obstruction. The value is in  $g\ C\ m^{-2}$ .

**Basis for assignment:** These values are variable BIOD5 in Century. The value was similar across biome types in the example files, and a single value was used here.

**Baseline values:**  
999.0 (for all units)

**Sensitivity values:**

- 1 – 699.0
- 2 – 799.0
- 3 – 899.0
- 4 – 999.0
- 5 – 1099.0
- 6 – 1199.0
- 7 – 1299.0

**Interpretation:** The parameter is directed toward forested land cover types, and changes in responses reflect that. Forests yield structural dead material sufficient to halve production, and other types do not. Annual evapotranspiration changed up to 5.5 cm. Temperate forests changed plant-available water by 0.2 cm. Soil organic carbon increased up to 300  $g\ m^{-2}$  (top). Live carbon density changed up to 280  $g\ m^{-2}$  (above). Herbaceous cover changed up to 5% in forested biomes. Other changes in facet cover were modest (left).

**Conclusion:** This parameter improves model fit in Century, and influences outputs in G-Range. Forested landscapes are not a focus of G-Range, but the parameter may be retained.

## 12. Radiation production coefficient

**Purpose:** The variable radiation\_production\_coefficient relates the solar radiation outside the atmosphere to monthly aboveground vegetation production. The coefficient is unitless.

**Basis for assignment:** These values are variable PRDX in Century 4.5. Example files for biomes from that model suggested the value was the same across biomes.

**Baseline values:**  
0.40 (for all units)

**Sensitivity values:**

- 1 – 0.25
- 2 – 0.30
- 3 – 0.35
- 4 – 0.40
- 5 – 0.45
- 6 – 0.50
- 7 – 0.55

**Interpretation:** Differences in radiation production coefficients cause large-scale changes in G-Range output. Annual net primary productivity (top) and other metrics often changed in lock-step with the coefficient. C:N ratio varied by almost 1 unit. The decomposition coefficient was 0.04 less with low coefficients. Herbaceous cover changed up to 20%, and trees a 10% increase in the savanna biome under a low coefficient (left).

**Conclusion:** This parameter is an important control on vegetation productivity. The value is appropriate to retain in G-Range, and must be set carefully given its sensitivity. The same value for all biomes is likely insufficient.

### 13. Fraction carbon to roots

**Purpose:** As one may guess, the variable `fraction_carbon_to_roots` is the fraction of carbon assimilated that it put to roots versus aboveground plant parts.

**Basis for assignment:** These values are variable FRTC in Century. Initial values were drawn from files distributed with Century. Numerous changes were made while adjusting the model.

**Baseline values:**

- 0.63, 0.63, 0.63 (unit 1)
- 0.63, 0.56, 0.56 (unit 2)

...

- 0.64, 0.50, 0.50 (unit 14)
- 0.75, 0.75, 0.75 (unit 15)

**Sensitivity values:**

- 1 – 0.500, 0.500, 0.500
- 2 – 0.567, 0.567, 0.567
- 3 – 0.633, 0.633, 0.633
- 4 – 0.700, 0.700, 0.700
- 5 – 0.767, 0.767, 0.767
- 6 – 0.833, 0.833, 0.833
- 7 – 0.900, 0.900, 0.900

**Interpretation:** As one may predict, the fraction of carbon assimilated that goes to roots has profound effects on the outcome of G-Range, especially over the broad range of values studied. Annual net primary production did not change greatly ( $< 70 \text{ g m}^{-2}$ ), but live carbon density increased up to  $1600 \text{ g m}^{-2}$  (above). C:N ratio declined by up to two units. Soil carbon responses were more variable, increasing  $500 \text{ g m}^{-2}$  and decreasing  $1700 \text{ g m}^{-2}$  in sensitivity test 7. Tree and shrub facets each changed up to 7%. Large changes in herbaceous facet cover were observed (left).

**Conclusion:** The parameter is important in this process-based model, and must be set carefully. The parameter should be retained.

## 14. Grazing effect

**Purpose:** The variable grazing\_effect is unlike most in G-Range, it is a categorical variable. Grazing effect, from 0 to 6, signifies which of seven functional responses to use to model grazing effects on production. See page 54 of Boone et al. (2011) for their definitions.

**Basis for assignment:** These values are variable GRZEFF in Century. A linear (type 1) response is used in most example biomes, and was used throughout here.

### Baseline values:

1 (all units)

### Sensitivity values:

1-0

2-1

3-2

4-3

5-4

6-5

7-6

**Interpretation:** The grazing functional response has important effects on the outputs from G-Range. Functional responses 0 through 3 led to relatively small changes in outputs, but 4-6 caused large changes. Effects on root to shoot ratios presumably led to those changes. Annual net primary productivity changed up to 120 g m<sup>-2</sup> (top). Leaf area index declined up to 0.3, and carbon to nitrogen ratio changed < 1 unit. Herb cover declined by as much as 22% in some landscape units under responses 5 and 6. Shrubs expanded in response (left), especially in tundra, and trees expanded as well.

**Conclusion:** The parameter provides flexibility in G-Range modeling. The parameter should be retained.

## 15. Effect of CO<sub>2</sub> on production

**Purpose:** The variable effect\_of\_co2\_on\_production is a unitless value that reflects the effect CO<sub>2</sub> has on the transpiration rates of plants. Under increased carbon dioxide, plants may close stomata and reduce transpiration rates.

**Basis for assignment:** The value is variable CO2ITR in Century. The typical value used in example files is 0.8. That is taken as the base response.

**Baseline values:**  
0.800 (all units)

**Sensitivity values:**

- 1 – 0.600
- 2 – 0.667
- 3 – 0.733
- 4 – 0.800
- 5 – 0.867
- 6 – 0.933
- 7 – 1.000

**Interpretation:** The effect of CO<sub>2</sub> on production has large effects on model output. Net primary productivity changed up to 150 g m<sup>-2</sup> (top), and plant-available soil water changed in the opposite pattern (above). Annual evapotranspiration changed in the same nature as primary productivity, up to 90 cm for tropical forests. Soil organic carbon had the similar pattern of change, with changes up to 850 g m<sup>-2</sup>, except for temperate boreal forests which changed up to 1750 g m<sup>-2</sup>. Herb cover changed markedly, up to 25% (left). Shrubs and trees changed less than 5%.

**Conclusion:** The parameter provides an opportunity for response to CO<sub>2</sub>, and should be retained.

## 16. Decomposition rate of structure litter by inverts

**Purpose:** The variable `decomp_rate_structural_litter_inverts` controls the rate of decomposition by invertebrates. The rates apply to the litter on the surface of the soil and below the surface, and so two values are supplied.

**Basis for assignment:** The value is variable DECINV in the Savanna model. The typical value used in applications was used here, but adjusted as the model was fit to observed data.

### Baseline values:

Various, from 1.1 to 6.5 for the first value, and 1.1 to 6.5 for the second value

### Sensitivity values:

- 1 – 1.0, 1.0
- 2 – 2.0, 2.0
- 3 – 3.0, 3.0
- 4 – 4.0, 4.0
- 5 – 5.0, 5.0
- 6 – 6.0, 6.0
- 7 – 7.0, 7.0

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Annual net primary productivity changed by up to 15 g m<sup>-2</sup>. Leaf area index changed little. Carbon to nitrogen ratio changed in a regular fashion (top). Annual evapotranspiration changed up to 3 cm (above). Soil temperature changed less than 0.5 degrees C. Shrub and tree cover did not change markedly, but herbaceous cover changed a great deal, 40% in either direction (left), with bare ground making up the difference.

**Conclusion:** The parameter yielded surprising changes to G-Range output, captures an important process, and should be retained.

## 17. Feces lignin

**Purpose:** The variable feces\_lignin describes the proportion of feces that are lignin. The intent is to allow partitioning of lignin.

**Basis for assignment:** The value is variable FECLIG in the Century model. The typical value used in examples released with that software was used.

**Baseline values:**

0.25

**Sensitivity values:**

1 – 0.19

2 – 0.21

3 – 0.23

4 – 0.25

5 – 0.27

6 – 0.29

7 – 0.31

**Interpretation:** Feces lignin is being read into G-Range and echoed to a file, but is not being used in any way in the model.

**Conclusion:** Lignin in feces should be tracked. The oversight will be corrected in the released version of G-Range.

## 18. Lignin content fraction and precipitation

**Purpose:** The variable lignin-content\_fraction\_and\_precip relates precipitation to the lignin content in materials, using two regression equations, one for aboveground and one for belowground.

**Basis for assignment:** The value is variable FLIGN in the Century model. The typical value used in examples released with that software was used.

**Baseline values:**  
0.0200, 0.0012, 0.2600, -0.0015 in all units

### Sensitivity values:

(for brevity, only slopes were adjusted)

- 1 - 0.0200, 0.0006, 0.2600, -0.0009
- 2 - 0.0200, 0.0008, 0.2600, -0.0011
- 3 - 0.0200, 0.0010, 0.2600, -0.0013
- 4 - 0.0200, 0.0012, 0.2600, -0.0015
- 5 - 0.0200, 0.0014, 0.2600, -0.0017
- 6 - 0.0200, 0.0016, 0.2600, -0.0019
- 7 - 0.0200, 0.0018, 0.2600, -0.0021

**Interpretation:** Extremely small changes in G-Range output were associated with changes in the slope of lignin content given precipitation. No changes occurred in facet covers.

**Conclusion:** The relationship appears correctly programmed within G-Range. The sensitivity values may vary too little, and the units in the code should be checked. But in general the parameter appears to change output in a minor way.

## 19. Fraction urine volatilized

**Purpose:** The variable fraction\_urine\_volatized describes the fraction of urine nitrogen deposited that is volatilized. The variable captures the idea that all nitrogen in urine is not entering the soil.

**Basis for assignment:** The value is variable URINEVOL in the Savanna model. The typical value used in applications was used here.

**Baseline values:**

0.20 in all units

**Sensitivity values:**

1 – 0.11

2 – 0.14

3 – 0.17

4 – 0.20

5 – 0.23

6 – 0.26

7 – 0.29

**Interpretation:** No changes in the biogeochemistry, productivity, or facet covers were associated with changes in the fraction of urine nitrogen that was volatilized.

**Conclusion:** The relationship appears correctly programmed within G-Range. The quantity of urine deposited and other logic should be checked. In general the parameter is appropriate to include in G-Range and should be explored more fully.

## 20. Precipitation nitrogen deposition

**Purpose:** The variable set `precip_n_deposition` defines a line that describes the rate of nitrogen deposition as it relates to precipitation.

**Basis for assignment:** The value is variable EPNFA in the Century model. The typical values used in example files distributed with that model are used here.

**Baseline values:**

0.05, 0.007 in all units

**Sensitivity values:**

(only the slope was changed, for brevity)

1 – 0.05, 0.001

2 – 0.05, 0.003

3 – 0.05, 0.005

4 – 0.05, 0.007

5 – 0.05, 0.009

6 – 0.05, 0.011

7 – 0.05, 0.013

**Interpretation:** Changes in the slope associating nitrogen deposition with precipitation led to modest changes in the results of G-Range. Soil temperature a fraction of a degree, and soil water changed little as well. Carbon to nitrogen ratio changed less than 0.2. Productivity changed up to 20 g m<sup>-2</sup> (left), and soil carbon changed a small amount (top). Herbs decreased up to 4% in tropical broadleaf evergreen forest. Other facets showed small changes as well.

**Conclusion:** The code within G-Range is incomplete. The parameters are not being used as the components of a line. The parameters will be retained and the code corrected prior to release of G-Range.

## 21. Precipitation nitrogen symbiotic

**Purpose:** The variable set `precip_n_symbiotic` defines a line that describes the rate of symbiotic nitrogen fixation as it relates to precipitation.

**Basis for assignment:** The value is variable EPNFS in the Century model. The typical values used in example files distributed with that model are used here.

**Baseline values**  
30.00, 0.0100 in all units

### Sensitivity values:

(only the slope was changed, for brevity)

- 1 – 30.00, 0.040
- 2 – 30.00, 0.060
- 3 – 30.00, 0.080
- 4 – 30.00, 0.010
- 5 – 30.00, 0.012
- 6 – 30.00, 0.014
- 7 – 30.00, 0.016

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- \* Trop. evergreen forest
- \* Trop. deciduous forest
- \* Temp. broad. ever. forest
- \* Temp. needle. ever. forest
- \* Temp. decid. forest
- \* Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** The parameter values relating precipitation to nitrogen symbiosis are read into the software and printed to an echo file, but is not used otherwise.

**Conclusion:** The code within G-Range is incomplete. The parameters are not being used as the components of a line. The parameters will be retained and the code corrected prior to release of G-Range.

## 22. Decomposition litter mixing between facets

**Purpose:** The variable set `decomp_litter_mix_facets` describes the degree to which litter mixes between facets within a given landscape cell. As litter falls, it may fall in neighboring facets. The value is a proportion.

**Basis for assignment:** The value is variable FLITRMIX in the Savanna model. The base values used in Savanna applications were used to initialize the model, and were then modified while fitting observed values..

### Baseline values

30.00, 0.0100 in all units

### Sensitivity values:

(only the slope was changed, for brevity)

- 1 – 30.00, 0.040
- 2 – 30.00, 0.060
- 3 – 30.00, 0.080
- 4 – 30.00, 0.010
- 5 – 30.00, 0.012
- 6 – 30.00, 0.014
- 7 – 30.00, 0.016

**Interpretation:** Changes in soil carbon (left) and live carbon density were modest (top). Soil temperature was a fraction of degree higher in dense shrub in sensitivity runs 1-3. Decomposition coefficients were essentially constant. Leaf area index changed less than 0.07. A change of up to 4.5% cover in the herb facet occurred, mirrors by changes in bare ground. Tree and shrub cover changed little.

**Conclusion:** Mixing of litter captures a process that influences outputs from G-Range. The parameter should be retained.

## 23a. Degree days phenology - Herbs

**Purpose:** The variable set degree\_days\_phen describes the relationship between heat accumulation (or degree days) and the phenology of herbs, shrubs, and trees. Three sets of values are given, four values comprising each set. These correspond with the four levels of phenology represented in G-Range.

**Basis for assignment:** The values were set initially based on a spatial heat accumulation surface from the Oak Ridge National Laboratory Spatial Data Access Tool. The values were then adjusted to improve fit with observed data.

### Baseline values

Unique values were used for each unit.

### Sensitivity values:

(herb values changed)

- 1 – 50, 100, 300, 600
- 2 – 150, 300, 600, 1000
- 3 – 250, 500, 1000, 1500
- 4 – 500, 800, 1200, 2000
- 5 – 750, 1000, 1500, 2500
- 6 – 1000, 1500, 2250, 3000
- 7 – 1500, 2500, 4000, 6000

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Degree days have the most important implications for the final phenology stage of herbs in G-Range. Herbs enter senescence based on the final value assigned. Because of that, changes in G-Range output were large. Annual evapotranspiration changed by up to 17%, and plant available soil water by 1.1 cm. Soil carbon (top) and net primary productivity changed markedly (above). Change in herbaceous cover was up to 26% (left). Trees and shrubs showed changes on par with those of herbs. Bare ground changed up to 30%.

**Conclusion:** The final value in phenology is most important at this point in G-Range, but phenology may play a larger role in the future.

## 23b. Degree days phenology - Shrubs

**Purpose:** The variable set degree\_days\_phen describes the relationship between heat accumulation (or degree days) and the phenology of herbs, shrubs, and trees. Three sets of values are given, four values comprising each set. These correspond with the four levels of phenology represented in G-Range.

**Basis for assignment:** The values were set initially based on a spatial heat accumulation surface from the Oak Ridge National Laboratory Spatial Data Access Tool. The values were then adjusted to improve fit with observed data.

### Baseline values

Unique values were used for each unit.

### Sensitivity values:

(shrubs only changed)

- 1 – 50, 100, 400, 800
- 2 – 150, 300, 700, 1200
- 3 – 250, 500, 1200, 2000
- 4 – 500, 800, 1500, 3000
- 5 – 750, 1500, 3000, 5000
- 6 – 1000, 1800, 3500, 7000
- 7 – 1500, 2500, 4000, 8000

**Interpretation:** Modest changes occurred throughout G-Range associated with changes in shrub phenology as it relates to degree day accumulation. Evapotranspiration changed less than 1 cm, and soil temperature changed less than half a degree. Annual net primary productivity changed up to 150 g m<sup>-2</sup>, in a pattern much like those above for live carbon density (top) and soil organic carbon (above). Herbaceous cover changed up to 15% in both directions (left), with those changes compensated by changes in bare ground.

**Conclusion:** Phenology may play a larger role in the future, but for now, it is a helpful trait to include in this process-based model.

### 23c. Degree days phenology - Trees

**Purpose:** The variable set degree\_days\_phen describes the relationship between heat accumulation (or degree days) and the phenology of herbs, shrubs, and trees. Three sets of values are given, four values comprising each set. These correspond with the four levels of phenology represented in G-Range.

**Basis for assignment:** The values were set initially based on a spatial heat accumulation surface from the Oak Ridge National Laboratory Spatial Data Access Tool. The values were then adjusted to improve fit with observed data.

#### Baseline values

Unique values were used for each unit.

#### Sensitivity values:

(trees only changed)

- 1 – 50, 100, 400, 800
- 2 – 150, 300, 700, 1200
- 3 – 250, 500, 1200, 2000
- 4 – 500, 800, 1500, 3000
- 5 – 750, 1500, 3000, 5000
- 6 – 1000, 1800, 3500, 7000
- 7 – 1500, 2500, 4000, 8000

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Some changes occurred throughout G-Range associated with changes in tree phenology as it relates to degree day accumulation. Evapotranspiration changed by more than 50 cm, and soil temperature changed up to 1 degree. Annual net primary productivity (top) and live carbon density (above) changed markedly. The tree facet cover changed up to 4% (left), as did the shrub facet cover. Herbs changed up to 25% in the savanna land cover type, and bare ground changed up to 13%.

**Conclusion:** Phenology may play a larger role in the future, but for now, it is a helpful trait to include in this process-based model.

## 24. Degree days reset

**Purpose:** The variable set degree\_days\_reset, when exceeded in a cell, changes the phenology stage of a plant type from the final value of 4 (senescence) to 0. That is, plants are reset to an early phenological stage.

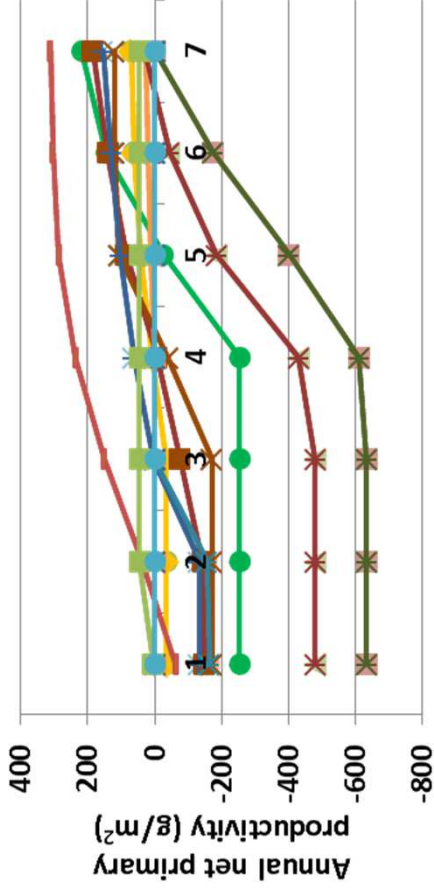

**Basis for assignment:** The values were set initially based on a spatial heat accumulation surface from the Oak Ridge National Laboratory Spatial Data Access Tool. The values were then adjusted to improve fit with observed data.

### Baseline values

Various, from 350, 350, 350 to 7000, 8000, 8000

### Sensitivity values:

- 1 – 350, 350, 350
- 2 – 1000, 1000, 1000
- 3 – 2000, 2000, 2000
- 4 – 3000, 3000, 3000
- 5 – 4500, 4500, 4500
- 6 – 6000, 6000, 6000
- 7 – 7500, 7500, 7500

**Interpretation:** Phenology reset is a difficult variable on which to do sensitivity analyses given the framework used here. But changes in output were large. Annual evapotranspiration declined by up to 62 cm, soil organic carbon changed up to 2250 g m<sup>-2</sup>. Live carbon density changed markedly (above), as did annual net primary productivity (top). Herbaceous cover decreased by up to 33% (left), and at the highest values used here, shrubs and trees increased in cover by up to 12%. Bare ground increased as herbaceous cover declined.

**Conclusion:** An ability to reset phenology is important in G-Range, and the variable set should be retained.

## 25. Tree site potential

**Purpose:** The variable tree\_site\_potential is from Century, and is used to describe the site potential of an area if trees are absent, and serves as a multiplier of that potential.

**Basis for assignment:** The values were set based on SITPOT-M from the Century example files, and were initialized to 1.0. During adjustment of the model the value for one landscape unit was changed..

### Baseline values

0.8 for unit 1  
1.0 for units 2-15

### Sensitivity values:

- 1 - 0.4
- 2 - 0.5
- 3 - 0.6
- 4 - 0.7
- 5 - 0.8
- 6 - 0.9
- 7 - 1.0

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Annual evapotranspiration changed by up to 0.8 cm, and soil temperature and decomposition coefficients by only fractions. Soil organic carbon changed by up to 270 g m<sup>-2</sup>. Plant available soil water (left) and net primary productivity (above) changed modestly, whereas carbon to nitrogen ratios changed significantly (top). Herbaceous cover increased up to 11% in tropical deciduous forest under low tree site potentials, and decreased by 8% at high potential for tropical evergreen forest. Shrub and tree cover changed little.

**Conclusion:** Tree site potential may be removed for brevity, if changes in herbaceous cover are sufficient using other parameters.

## 26. Maximum symbiotic N fixation ratio

**Purpose:** The variable `max_symbiotic_n_fixation_ratio` describes the maximum nitrogen that is fixed through symbiotic relationships. The value is a ratio, but may be thought of as being in grams nitrogen for grams carbon of new growth.

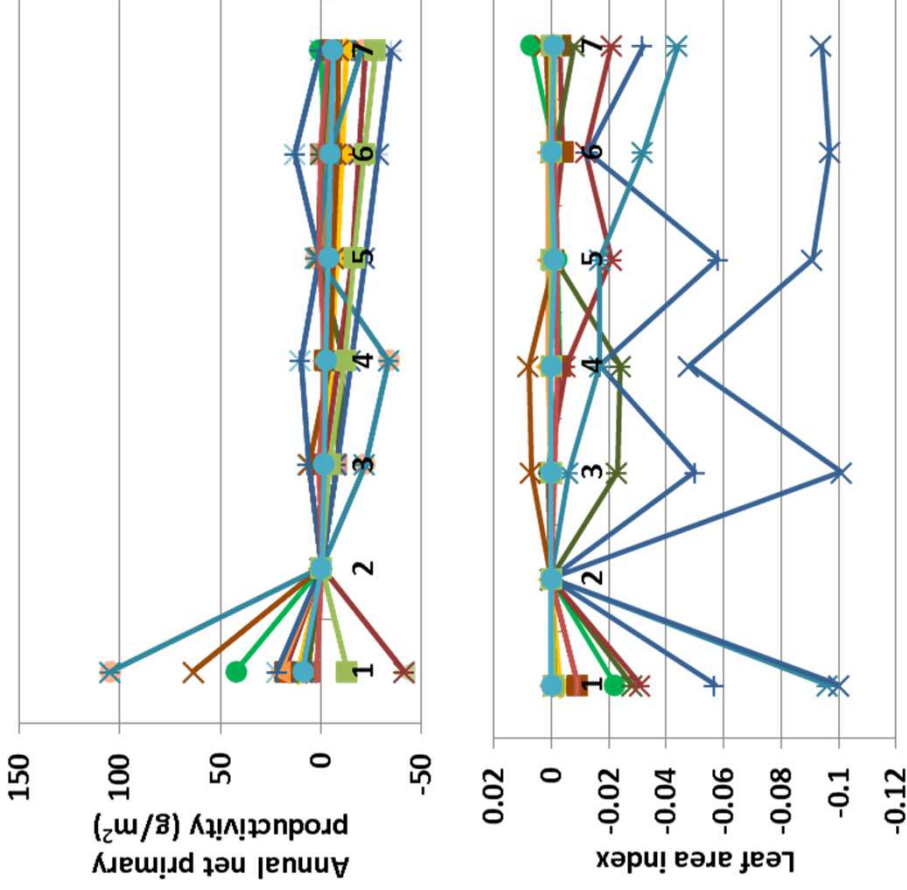

**Basis for assignment:** The values were set based on SNFXMX from the Century example files, and were initialized to the value used in those examples.

### Baseline values

0.001 for all units

### Sensitivity values:

- 1 – 0.000
- 2 – 0.001
- 3 – 0.002
- 4 – 0.003
- 5 – 0.004
- 6 – 0.005
- 7 – 0.006

### Interpretation:

Changes in response to varying the maximum symbiotic nitrogen fixation ratio were modest. Evapotranspiration changed up to 0.3 cm, and soil temperature a quarter of a degree. Soil organic carbon increased 17 g m<sup>-2</sup> in temperate broadleaf evergreen forests. Carbon to nitrogen ratio mostly increased, up to 0.37 units. Live carbon density mostly declined, as did leaf area index (above). Herbaceous cover changed by up to 7% (left), and shrub and tree cover changed less than 1%.

**Conclusion:** The parameter captures a known process in ecosystems, and may be retained, although the values assessed led to modest differences in G-Range output.

## 27a. Minimum C to N ratio - Herbs

**Purpose:** The variable set minimum\_c\_n\_ratio describes the minimum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLCIS and AGLIVE in the Century example files.

### Baseline values

10., 13., 0., 0., 0., 13., 20., 30., 50., 60., 15., 21., 32., 52., 52 for all units

### Sensitivity values:

(herbs only adjusted, last 3 values not used)

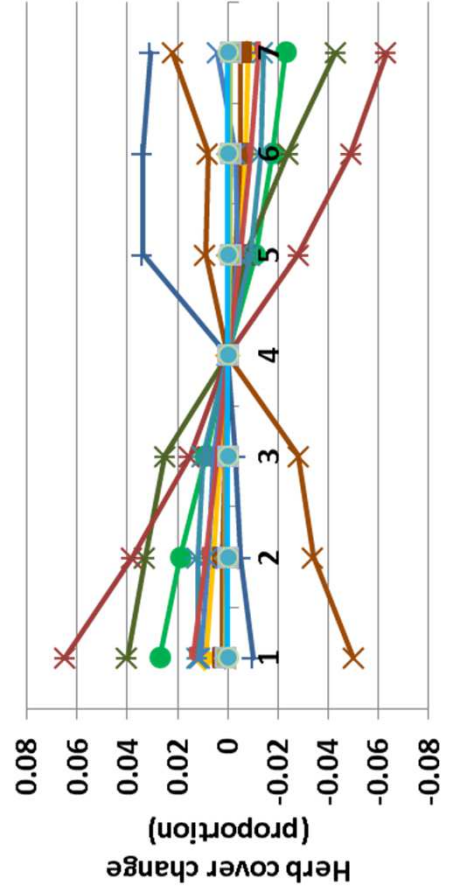

- 1 - 7, 10, 0, 0, 0
- 2 - 8, 11, 0, 0, 0
- 3 - 9, 12, 0, 0, 0
- 4 - 10, 13, 0, 0, 0
- 5 - 11, 14, 0, 0, 0
- 6 - 12, 15, 0, 0, 0
- 7 - 13, 16, 0, 0, 0

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Responses from the model suggest that the carbon to nitrogen ratio in G-Range is rarely trimmed to the minimum for herbs. Carbon to nitrogen ratio changed by up to 0.33 (above), and net primary productivity by up to 27 g m<sup>-2</sup> (top). Annual evapotranspiration changed up to 0.25 cm. Plant available soil water changed less than 0.01 cm. Soil organic carbon mostly increased, up to 175 g m<sup>-2</sup> in temperate broadleaf evergreen forests. Herbaceous cover changed up to 7% (left). Shrub and tree facets changed very little.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 27b. Minimum C to N ratio - Shrubs

**Purpose:** The variable set minimum\_c\_n\_ratio describes the minimum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLCIS and AGLIVE in the Century example files.

### Baseline values

10., 13., 0., 0., 13., 20., 30., 50., 60., 15., 21., 32., 52., 52. for all units

### Sensitivity values:

(shrubs only adjusted)

- 1 - 10, 14, 20, 38, 48
- 2 - 11, 16, 23, 42, 52
- 3 - 12, 18, 27, 46, 56
- 4 - 13, 20, 30, 50, 60
- 5 - 14, 22, 33, 54, 64
- 6 - 15, 24, 36, 58, 68
- 7 - 16, 26, 39, 62, 72

**Interpretation:** As elsewhere, potential evapotranspiration and snow water equivalent are not sensitivity to this parameter. Soil temperature changes a fraction of a degree. Carbon to nitrogen ratio changed up to 0.37 units (left). Annual net primary productivity and soil organic carbon change a small amount (top, above). Leaf area index changed up to 0.07 units. Coefficients associated with decomposition were essentially unchanged. Herbaceous cover changed up to 4%. Shrub and tree facets changed a fraction of a percent.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 27c. Minimum C to N ratio - Trees

**Purpose:** The variable set minimum\_c\_n\_ratio describes the minimum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLCIS and AGLIVE in the Century example files.

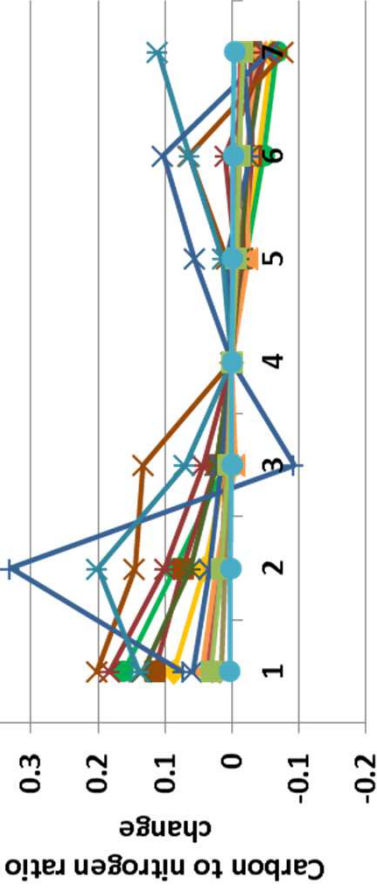

### Baseline values

10., 13., 0., 0., 13., 20., 30., 50., 60., 15., 21., 32., 52., 52 for all units

### Sensitivity values:

(trees only adjusted)

- 1 - 12, 15, 23, 40, 40
- 2 - 13, 17, 26, 44, 44
- 3 - 14, 19, 29, 48, 48
- 4 - 15, 21, 32, 52, 52
- 5 - 16, 23, 35, 56, 56
- 6 - 17, 25, 38, 60, 60
- 7 - 18, 27, 41, 64, 64

**Interpretation:** Responses from the model suggest that the carbon to nitrogen ratio in G-Range is rarely trimmed to the minimum for herbs. Carbon to nitrogen ratio changed by up to 0.33 (above), and net primary productivity by up to 27 g m<sup>-2</sup> (top). Annual evapotranspiration changed up to 0.25 cm. Plant available soil water changed less than 0.01 cm. Soil organic carbon mostly increased, up to 175 g m<sup>-2</sup> in temperate broadleaf evergreen forests. Herbaceous cover changed up to 7% (left). Shrub and tree facets changed very little.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 28a. Maximum C to N ratio - Herbs

**Purpose:** The variable set maximum\_c\_n\_ratio describes the maximum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLCIS and AGLIVE in the Century example files.

### Baseline values

30., 33., 0., 0., 33., 40., 50., 80., 90., 35., 51., 62., 92., 95. for all units

### Sensitivity values:

(herbs only adjusted, last 3 values not used)

- 1 - 24, 27, 0, 0, 0
- 2 - 26, 29, 0, 0, 0
- 3 - 28, 31, 0, 0, 0
- 4 - 30, 33, 0, 0, 0
- 5 - 32, 35, 0, 0, 0
- 6 - 34, 37, 0, 0, 0
- 7 - 36, 39, 0, 0, 0

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. ever. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes associated with maximum c to n ratio sensitivity are modest. Annual evapotranspiration changed less than 0.2 cm, and temperature a small fraction of a degree. Annual net primary productivity changes up to 20 g m<sup>-2</sup> (top). Carbon density changed up to 57 g m<sup>-2</sup> in temperature forests, up to 17 g m<sup>-2</sup> in other biomes. Herbaceous cover changed up to 4%. Shrub and tree facets changed a fraction of a percent. Bare ground expands as herbaceous cover declines.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 28b. Maximum C to N ratio - Shrubs

**Purpose:** The variable set maximum\_c\_n\_ratio describes the maximum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLICIS and AGLIVE in the Century example files.

### Baseline values

30., 33., 0., 0., 33., 40., 50., 80., 90., 35., 51., 62., 92., 95. for all units

### Sensitivity values:

(shrubs only adjusted)

- 1 – 27, 34, 41, 68, 78
- 2 – 29, 36, 44, 72, 82
- 3 – 31, 38, 47, 76, 86
- 4 – 33, 40, 50, 80, 90
- 5 – 35, 42, 53, 84, 94
- 6 – 37, 44, 56, 88, 98
- 7 – 39, 46, 59, 91, 102

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- ◆ Trop. evergreen forest
- ◆ Trop. deciduous forest
- ◆ Temp. broad. ever. forest
- ◆ Temp. needle. ever. forest
- ◆ Temp. decid. forest
- ◆ Boreal decid. forest
- ◆ Mixed forest
- ◆ Tundra
- ◆ Polar

**Interpretation:** In general, changes in responses were minimal, suggesting that maximum carbon to nitrogen ratios were not being enforced in modeling very often, which is good. Decomposition coefficients did not change. Carbon to nitrogen ratios changed a fraction (top), and live carbon density was changed little, except in evergreen forests. Herbaceous cover changed up to 4%, with an accompanying change in bare ground cover (left). Shrub and tree facets changed a fraction of a percent.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 28c. Maximum C to N ratio - Trees

**Purpose:** The variable set maximum\_c\_n\_ratio describes the maximum carbon to nitrogen ratio that may occur in simulated plant parts. Three groups of five values are used, one set for each facet, and the five values represent leaves, fine roots, fine branches, coarse branches, and coarse roots.

**Basis for assignment:** The values were set based on AGLCIS and AGLIVE in the Century example files.

### Baseline values

30., 33., 0., 0., 33., 40., 50., 80., 90., 35., 51., 62., 92., 95. for all units

### Sensitivity values:

(trees only adjusted)

1 - 29, 45, 53, 80, 83

2 - 31, 47, 56, 84, 87

3 - 33, 49, 59, 88, 91

4 - 35, 51, 62, 92, 95

5 - 37, 53, 65, 96, 99

6 - 39, 55, 68, 100, 103

7 - 41, 57, 71, 104, 107

**Interpretation:** Few sizable changes occurred when maximum carbon to nitrogen ratio in trees was changed. Evapotranspiration changed less than 0.1 cm, and decomposition coefficients did not change. Soil organic carbon changed little, mostly a modest increase in temperate boreal evergreen forest (left). Net primary productivity changed very little (top), as did leaf area index (above). Herbaceous cover changed very little, expect for a 4% change in temperate broadleaf evergreen forest. Shrubs and trees essentially were unchanged.

**Conclusion:** The parameter set helps constrain model results and should be retained.

## 29. Maximum leaf area index

**Purpose:** The variable maximum\_leaf\_area\_index provides an upper limit to leaf area index. An optimum leaf area index is calculated based on the maximum value, plus coarse branch carbon biomass and the k leaf area index coefficient. If the result is below 0.1, the optimum leaf area index is set to 0.1.

**Basis for assignment:** The values were set based on MAXLAI within the example files distributed with the Century model.

### Baseline values

20.0 for units 1 to 8

6.0 for units 9 to 11

4.0 for units 12 to 15

### Sensitivity values:

1 – 3.0

2 – 6.0

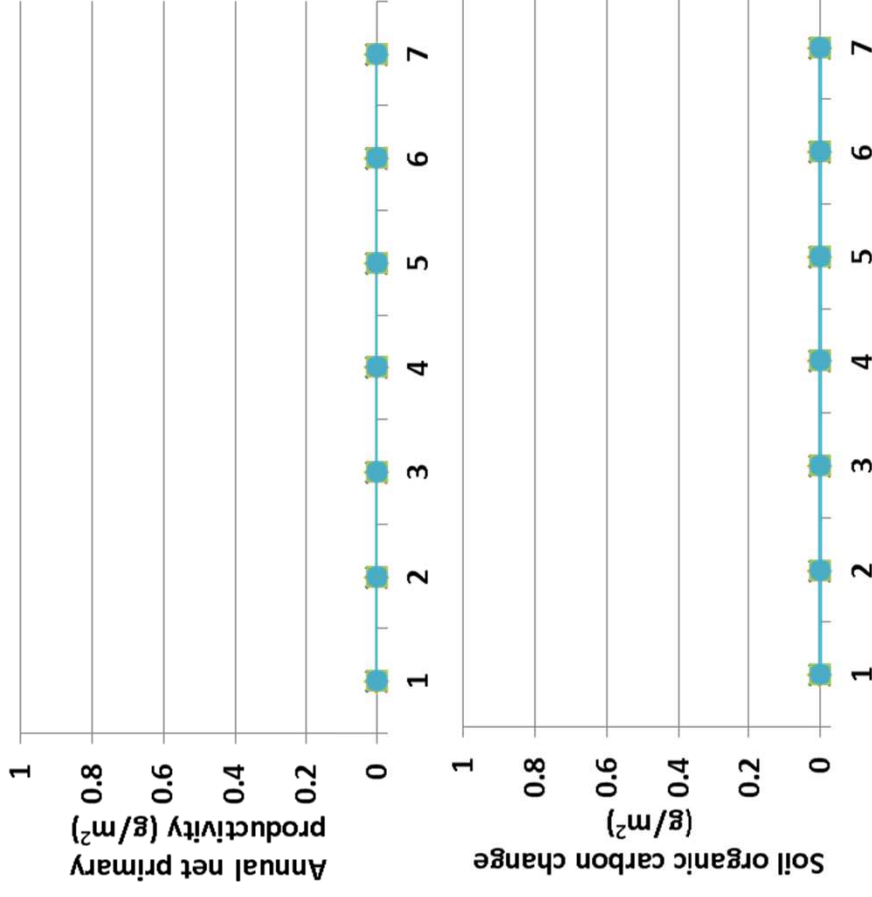

3 – 9.0

4 – 12.0

5 – 15.0

6 – 18.0

7 – 21.0

**Interpretation:** Simulation results were not sensitive to changes in maximum leaf area index. That is surprising given its use in the model, to for the foundation for calculating an optimum leaf area index. I have confirmed that the variable is being read in correctly, and will continue research to verify that calculations are being made correctly.

**Conclusion:** The parameter is central to representing leaf area index in G-Range, and should be retained. More research is required to verify its use in the model.

### 30. K leaf area index

**Purpose:** The variable k\_leaf\_area\_index is a value used to indicate when half of the maximum leaf area index is attained, in gC m<sup>-2</sup>. The value is used when calculating an optimum leaf area index for a given facet.

**Basis for assignment:** The values were set based on KLAI within the example files distributed with the Century model.

**Baseline values**  
2000 for all units

**Sensitivity values:**

- 1 – 1400
  - 2 – 1600
  - 3 – 1800
  - 4 – 2000
  - 5 – 2200
  - 6 – 2400
  - 7 – 2600
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. deciduous forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** Simulation results were not sensitive to changes in K leaf area index. That is surprising given its use in the model, to form the foundation for calculating an optimum leaf area index. I have confirmed that the variable is being read in correctly, and will continue research to verify that calculations are being made correctly.

**Conclusion:** The parameter is central to representing leaf area index in G-Range, and should be retained. More research is required to verify its use in the model.

### 31. Biomass to leaf area index factor

**Purpose:** The variable biomass\_to\_leaf\_area\_index\_factor is a conversion coefficient that converts biomass of leaves to a leaf area index. The coefficient applies to each of the facets, and is based on carbon in leaves, and so is multiplied by a conversion prior to use.

**Basis for assignment:** The values were set based on BTOLAI within the example files distributed with the Century model. They were modified to improve model fit.

#### Baseline values

Various values from 0.0029 to 0.0158

#### Sensitivity values:

- 1 - 0.001
- 2 - 0.004
- 3 - 0.007
- 4 - 0.010
- 5 - 0.013
- 6 - 0.016
- 7 - 0.019

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- ◆ Trop. evergreen forest
- ◆ Trop. deciduous forest
- ◆ Temp. broad. ever. forest
- ◆ Temp. needle. ever. forest
- ◆ Temp. decid. forest
- ◆ Boreal decid. forest
- ◆ Mixed forest
- ◆ Tundra
- ◆ Polar

**Interpretation:** Large changes occurred in G-Range outputs in response to changes in biomass to leaf area index factor. LAI changed linearly with the coefficient, as expected (left). Other changes were non-linear, such as live carbon density (top) and annual evapotranspiration (above). Net primary productivity changed by 220 g m<sup>-2</sup>. Herb, shrub, and tree cover increased up to 20% when the coefficient was 0.001, and declined up to 10% for woody plants, and 27% for herbs. Bare ground increased up to 38%.

**Conclusion:** The parameter is required to convert leaf biomass to leaf area index, and should be retained. The high sensitivity of the model to variation in the parameter suggests that it be well defined.

## 32. Annual fraction volatilized nitrogen

**Purpose:** The variable `annual_fraction_volatilized_n` is a unitless coefficient reflecting the annual fraction of nitrogen that is volatilized. Mineralized nitrogen is multiplied by this coefficient to represent losses to volatilization.

**Basis for assignment:** The values were set based on VLOSSE within the example files distributed with the Century model.

### Baseline values

0.020 for units 1 to 13

0.050 for units 14 and 15

### Sensitivity values:

1 – 0.00

2 – 0.01

3 – 0.02

4 – 0.03

5 – 0.04

6 – 0.05

7 – 0.06

**Interpretation:** The fraction of nitrogen volatilized is fairly small, and that is reflected in the outputs from G-Range. Annual evapotranspiration changed less than 0.1 cm, and soil temperature and plant available water changed little. Carbon to nitrogen ratio is the only nitrogen-centric measure assessed, and changed up to 0.025, except for temperate needle evergreen forest (top). Annual net primary productivity changed up to 25 g m<sup>-2</sup> (above). Herbaceous cover changed very little, except for temperate broadleaf evergreen forest, which declined 1.5% (left).

**Conclusion:** The parameter describes a process that should be represented in G-Range, and should be retained.

### 33. Maximum root death rate

**Purpose:** The variable maximum\_root\_death\_rate defines the initial maximum death rate of fine roots. The death rate is then modified based on water availability and other constraints.

**Basis for assignment:** The values were inferred and adjusted to improve model fit.

#### Baseline values

0.20, 0.20, 0.20 for units 1 and 2  
 0.30, 0.30, 0.30 for units 3 through 15

#### Sensitivity values:

- 1 – 0.10, 0.10, 0.10
- 2 – 0.15, 0.15, 0.15
- 3 – 0.20, 0.20, 0.20
- 4 – 0.25, 0.25, 0.25
- 5 – 0.30, 0.30, 0.30
- 6 – 0.35, 0.35, 0.35
- 7 – 0.40, 0.40, 0.40

**Interpretation:** On inspection of the G-Range code we find that the parameter is only applicable to herbaceous plants. Fine root death rate is controlled in woody plants by other means. Changes to facet cover were large, such as the almost 30% change in herbaceous cover (left). Leaf area carbon density changed markedly (top), but other changes were more modest, such as soil organic carbon (above), leaf area index, which changed less than 0.07, and annual net primary productivity, which changed up to 25 g m<sup>-2</sup>.

**Conclusion:** The parameter is important to determine herb death rate. The parameters for woody plants may be removed, and the parameter name changed.

### 34a. Shoot death rate – Water stress

**Purpose:** The variable set shoot\_death\_rate controls death rate of herbaceous shoots from three sources, 1) water stress, 2) phenological limits, and 3) shading. The first three values are death rates, the last is a carbon concentration reflecting shading by herbaceous leaves.

**Basis for assignment:** Initialized based on FSDETH in the example files of Century, then adjusted to improve model fit.

#### Baseline values

Various values. Two selected units are:  
 0.009, 0.150, 0.020, 1800.0 for unit 1  
 0.012, 0.180, 0.012, 1200.0 for unit 15

#### Sensitivity values:

(adjusting water stress only)

- 1 – 0.004
- 2 – 0.007
- 3 – 0.010
- 4 – 0.013
- 5 – 0.016
- 6 – 0.019
- 7 – 0.022

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. ever. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in water stress caused modest but reasonable changes to G-Range outputs. Annual evapotranspiration changed less than 2 cm, and soil temperature changed little. Soil organic carbon change about 100 g m<sup>-2</sup>, except for temperate boreal evergreen forest, which increased to 210 g m<sup>-2</sup>. Leaf carbon density changed in-step with water stress sensitivity (top), and annual net primary productivity changed relatively little (above). Herbaceous facet cover changed up to 8% with changes in sensitivity to water stress (left). Woody plants changed little.

**Conclusion:** The parameter is important in describing herbaceous shoot mortality and will be retained.

### 34b. Shoot death rate – Phenology

**Purpose:** The variable set shoot\_death\_rate controls death rate of herbaceous shoots from three sources, 1) water stress, 2) phenological limits, and 3) shading. The first three values are death rates, the last is a carbon concentration reflecting shading by herbaceous leaves.

**Basis for assignment:** Initialized based on FSDETH in the example files of Century, then adjusted to improve model fit.

#### Baseline values

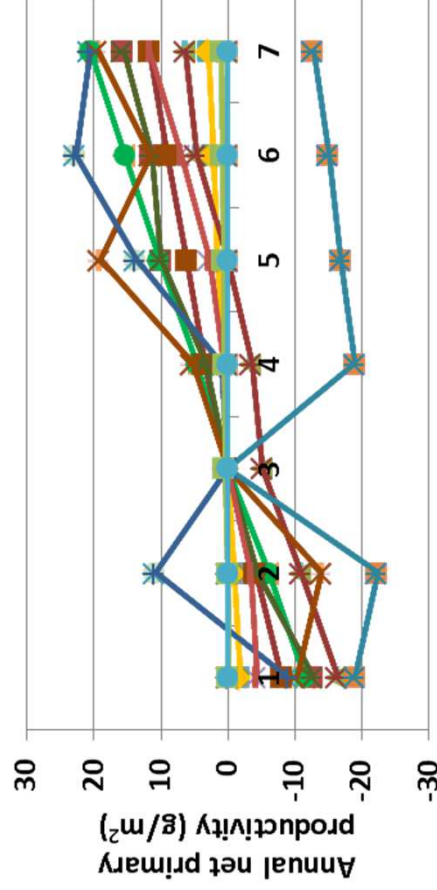

Various values. Two selected units are:  
 0.009, 0.150, 0.020, 1800.0 for unit 1  
 0.012, 0.180, 0.012, 1200.0 for unit 15

#### Sensitivity values:

(adjusting phenology only)

- 1 – 0.11
- 2 – 0.13
- 3 – 0.15
- 4 – 0.17
- 5 – 0.19
- 6 – 0.21
- 7 – 0.23

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in live carbon density were up to 280 g m<sup>-2</sup>, as shoot density changed. Leaf area index change less than 0.8. Annual evapotranspiration changed up to 4 cm (top), and plant available water changed less than 0.07 cm. Annual net primary productivity showed modest changes (above). Herbaceous cover changed up to 12% in response to changes in death rate associated with phenology (left). Changes to woody cover were very small. As is typical, changes in herbaceous cover were offset by changes in bare ground cover.

**Conclusion:** The parameter is important in describing herbaceous shoot mortality and will be retained.

### 34c. Shoot death rate – Shading

**Purpose:** The variable set shoot\_death\_rate controls death rate of herbaceous shoots from three sources, 1) water stress, 2) phenological limits, and 3) shading. The first three values are death rates, the last is a carbon concentration reflecting shading by herbaceous leaves.

**Basis for assignment:** Initialized based on FSDETH in the example files of Century, then adjusted to improve model fit.

#### Baseline values

Various values. Two selected units are:  
 0.009, 0.150, 0.020, 1800.0 for unit 1  
 0.012, 0.180, 0.012, 1200.0 for unit 15

#### Sensitivity values:

(adjusting shading only)

- 1 – 0.005
- 2 – 0.009
- 3 – 0.013
- 4 – 0.017
- 5 – 0.021
- 6 – 0.025
- 7 – 0.029

**Interpretation:** There were almost no changes in G-Range output associated with changes to shading from herbaceous leaves on shoot death rate. This is related to the binary nature of inclusion of the shading effect – if carbon density exceeds the fourth value given, the effect is included, if it does not it is not used. Facet covers did not change in response to changes in herbaceous shoot death rate associated with phenology.

**Conclusion:** The parameter is important in describing herbaceous shoot mortality and will be retained.

### 35. Proportion annuals

**Purpose:** The variable proportion\_annuals reflects the proportion of herbaceous vegetation that is annuals versus the proportion that is perennial.

**Basis for assignment:** The values were inferred, but are weakly defined. More research is needed to improve their assignment.

**Baseline values**

- 0.40 for unit 1
- 0.20 for units 2 to 15

**Sensitivity values:**

- 1 – 0.07
- 2 – 0.13
- 3 – 0.19
- 4 – 0.25
- 5 – 0.31
- 6 – 0.37
- 7 – 0.43

**Interpretation:** Changes due to proportion of annuals led to some changes in G-Range output that were smaller than expected, but these annual summaries do not capture within year differences. Annual evapotranspiration changed up to 2 cm, and soil temperature changed little. Soil organic carbon changed up to 400 g m<sup>-2</sup>. Carbon to nitrogen ratio changed less than 0.4 (above) and leaf area index over 0.6 units (top). Herbaceous cover changed up to 12%. Woody types changed little.

**Conclusion:** The parameter represents a critical component of ecosystems and influences intra-annual system dynamics (though not represented here). Values assigned should be refined.

### 36. Month to remove annuals

**Purpose:** Annuals die at a rate set by an entry in shoot\_death\_rate (here, entry 34b), but that rate may not ensure all annuals are removed each year. Month\_to\_remove\_annuals is the period when all remaining annuals are killed.

**Basis for assignment:** The same value is used throughout, and is set to December. More research into ends of seasons would be beneficial.

#### Baseline values

12

#### Sensitivity values:

(note unequal intervals)

- 1 - 1 Grass
- 2 - 2 Savanna
- 3 - 4 Dense shrub
- 4 - 6 Open shrub
- 5 - 8 Desert
- 6 - 10 Trop. evergreen forest
- 7 - 12 Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in G-Range output in response to different months to remove annuals were small. This is expected, given that the rate of death due to phenology should leave few herbs to be removed when the month is reached. For example, carbon to nitrogen ratio changed up to 0.15, and leaf carbon density changed up to 60 g m<sup>-2</sup>. Annual net primary productivity changed less than 20 g m<sup>-2</sup>. Herbaceous cover changed up to 5% (left). Woody types changed very little.

**Conclusion:** The parameter is an important and easily interpretable control to help herbs be well represented, and will be retained.

### 37a. Relative seed production - Herbs

**Purpose:** The variable set relative\_seed\_production provides an index to the initial number of seeds produced by herbs, shrubs, and trees. For each facet, the value is then modified based on controls on establishment, such as limitations due to water or litter.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, from a low of 1350.0, 400.0, 400.0 for the polar unit to 5300.0, 8050.0, 8050.0 for trop. ever. forest.

#### Sensitivity values:

(herbaceous values changed only)

- 1 – 2000
- 2 – 3000
- 3 – 4000
- 4 – 5000
- 5 – 6000
- 6 – 7000
- 7 – 8000

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed decid. forest
- Tundra
- Polar

**Interpretation:** As expected, changes in relative seed production can have profound effects on facet cover. Herbaceous cover declined by more than 30% at low relative seed production, and increased by 90% at the highest levels (left). Shrubs and trees did not change significantly. Changes in biochemistry modeling were more modest. Evapotranspiration and temperature changed little. Annual net primary productivity changed less than 25 g m<sup>-2</sup> (top) and soil organic carbon changed up to 200 g m<sup>-2</sup> (above).

**Conclusion:** The parameter is an important control on facet cover, and should be retained.

### 37b. Relative seed production - Shrubs

**Purpose:** The variable set relative\_seed\_production provides an index to the initial number of seeds produced by herbs, shrubs, and trees. For each facet, the value is then modified based on controls on establishment, such as limitations due to water or litter.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

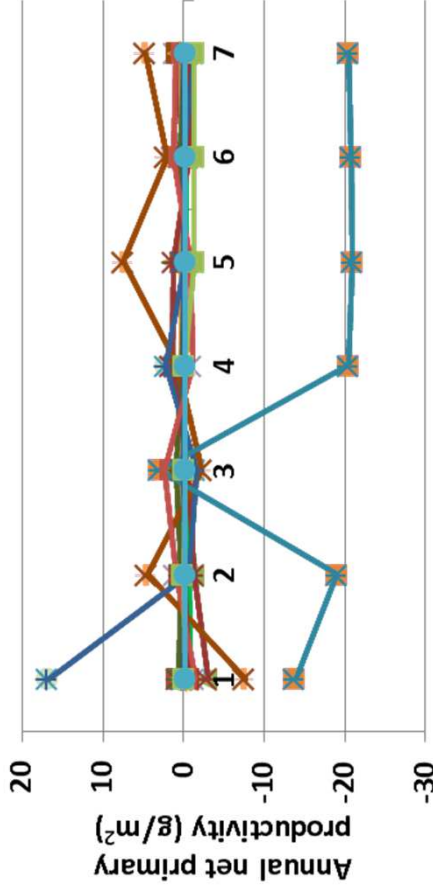

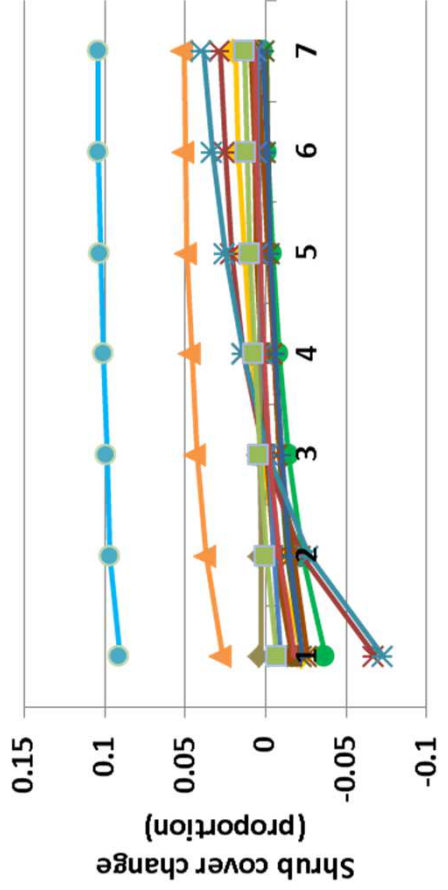

Various values, from a low of 1350.0, 400.0, 400.0 for the polar unit to 5300.0, 8050.0, 8050.0 for trop. ever. forest.

#### Sensitivity values:

(shrub values changed only)

- 1 – 2000
- 2 – 3000
- 3 – 4000
- 4 – 5000
- 5 – 6000
- 6 – 7000
- 7 – 8000

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Shrub cover changed up to 11% in response to changes in relative seed production (left), and herbs change in an opposite fashion to shrubs up to 10%. Tree facet cover changed little; changes in bare ground offset other facet changes. Changes in the biochemistry were small, such as up to 70 g m<sup>-2</sup> change in soil organic carbon (top), and a change in annual net primary productivity up to 22 g m<sup>-2</sup>. Plant soil water changed very little, and decomposition coefficients did not change.

**Conclusion:** The parameter is an important control on facet cover, and should be retained.

### 37c. Relative seed production - Trees

**Purpose:** The variable set relative\_seed\_production provides an index to the initial number of seeds produced by herbs, shrubs, and trees. For each facet, the value is then modified based on controls on establishment, such as limitations due to water or litter.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, from a low of 1350.0, 400.0, 400.0 for the polar unit to 5300.0, 8050.0, 8050.0 for trop. ever. forest.

#### Sensitivity values:

(tree values changed only)

- 1 – 2000
- 2 – 3000
- 3 – 4000
- 4 – 5000
- 5 – 6000
- 6 – 7000
- 7 – 8000

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. ever. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Tree cover declined up to 10% when relative seed production was very low. Shrub cover changed by up to 5%, and herbaceous cover changed up to 8%, both increasing as tree cover declined. Leaf area index changed up to 0.04, and annual net primary productivity by up to 15 g m<sup>-2</sup>. Carbon to nitrogen ratio changed up to 0.22 (top), and soil organic carbon by up to 75 g m<sup>-2</sup>. Other changes were quite small.

**Conclusion:** The parameter is an important control on facet cover, and should be retained.

### 38a. Water effect on establishment - Herbs

**Purpose:** The variable set `water_effect_on_establishment` creates a multiplier for the relative seed production rate based on the ratio of plant available water to potential evapotranspiration. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

0.37, 0.50, 3.0, 1.00, 0.0, 0.76, 6.0, 1.00, 1.0, 0.67, 4.0, 1.00

#### Sensitivity values:

(herb lower x values changed only)

1 – 0.00

2 – 0.10

3 – 0.20

4 – 0.30

5 – 0.40

6 – 0.50

7 – 0.60

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- \* Trop. evergreen forest
- \* Trop. deciduous forest
- \* Temp. broad. ever. forest
- \* Temp. needle. ever. forest
- \* Temp. decid. forest
- \* Boreal decid. forest
- \* Mixed forest
- Tundra
- Polar

**Interpretation:** Herbaceous cover changed up to almost 40% for most landscape units, except for desert, where a reduction in water stress lead to herbaceous cover changing up to 90%. Shrubs and trees were essentially unchanged. Parameters affecting establishment had little effect on biochemical modeling, as expected. Annual evapotranspiration, soil temperature, potential evapotranspiration, etc, changed little. Soil organic carbon mostly changed up to 220 g m<sup>-2</sup> (top). Live carbon density changed by up to 42 g m<sup>-2</sup>.

**Conclusion:** The parameter is important to reflect the effect of water limitations on facet cover, and should be retained.

### 38b. Water effect on establishment - Shrubs

**Purpose:** The variable set `water_effect_on_establishment` creates a multiplier for the relative seed production rate based on the ratio of plant available water to potential evapotranspiration. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

0.37, 0.50, 3.0, 1.00, 1.0, 0.76, 6.0, 1.00, 1.0, 0.67, 4.0, 1.00

#### Sensitivity values:

- ✱ Temp. decid. forest
- ✱ Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Shrub cover changed less in response to changes in water stress on establishment than did herbaceous plants, as expected. Temperate forest shrub cover declined up to 4.5% (left). Tree and bare ground cover changed little; the change in shrub cover was offset by changes in herbaceous cover. Other changes were fairly small. Annual net primary productivity changed less than 20 g m<sup>-2</sup>, and carbon to nitrogen ratio changed less than 0.35. Soil organic carbon changed up to 80 g m<sup>-2</sup> (above), and live carbon density changed relatively little (top).

**Conclusion:** The parameter is important to reflect the effect of water limitations on facet cover, and should be retained.

### 38c. Water effect on establishment - Trees

**Purpose:** The variable set `water_effect_on_establishment` creates a multiplier for the relative seed production rate based on the ratio of plant available water to potential evapotranspiration. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

0.37, 0.50, 3.0, 1.00, 1.0, 0.76, 6.0, 1.00, 0.67, 4.0, 1.00

#### Sensitivity values:

(tree lower y values changed only)

1 – 0.40

2 – 0.45

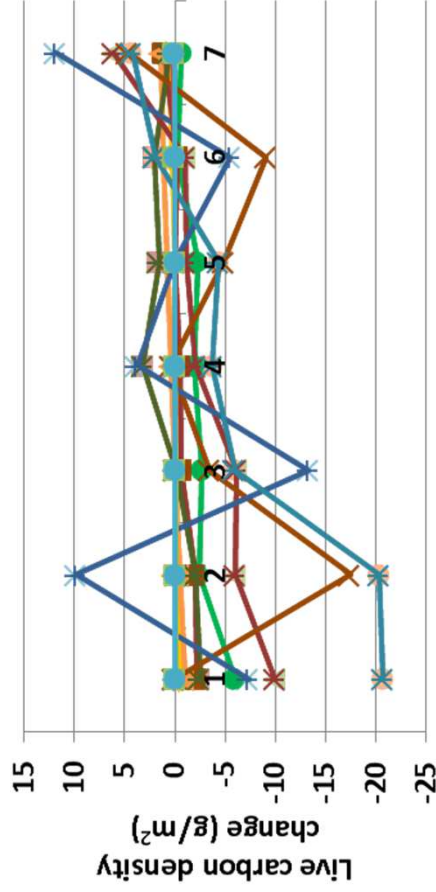

3 – 0.50

4 – 0.55

5 – 0.60

6 – 0.65

7 – 0.70

**Interpretation:** Tree cover changed only a small amount due to changes in water stress, with most changes less than 1.5%, except for tropical and temperate deciduous forests (left). Shrubs changed up to 2.4%, and herbs changed up to 7%. Other changes in G-Range output were fairly modest. Evapotranspiration, soil temperature, plant-available water, and decomposition coefficients changed little. Soil organic carbon increased up to 70 g m<sup>-2</sup>. Annual net primary production changed up to 15 g m<sup>-2</sup>. Live carbon density (above) changed up to 22 g m<sup>-2</sup>, and leaf area index changed little (top).

**Conclusion:** The parameter is important to reflect the effect of water limitations on facet cover, and should be retained.

### 39a. Herb root effect on establishment - Herbs

**Purpose:** The variable set herb\_root\_effect\_on\_establishment creates a multiplier for the relative seed production rate based on the biomass of herbaceous roots, reflecting root crowding. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

50.0, 1., 300., 0.50, 100.0, 1., 500.0, 0.0, 150.0, 1., 600.0, 0.0

#### Sensitivity values:

(herb upper x values changed only)

- 1 – 200
  - 2 – 250
  - 3 – 300
  - 4 – 350
  - 5 – 400
  - 6 – 450
  - 7 – 500
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. deciduous forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** Changes in biogeochemical results from G-Range were very small in response to changes in herbaceous root effects on the establishment of herbs. Examples shown include annual evapotranspiration that changed a fraction, and live carbon density that changed less than 13 g m<sup>-2</sup>. Net primary productivity was essentially unchanged. Herbaceous cover changed little (up to 2%) with changes in herb root effects on establishment. Woody facets did not change at all.

**Conclusion:** The parameter is important to reflect the effect of competition for space by roots on facet cover, which may be important in some locations.

### 39b. Herb root effect on establishment - Shrubs

**Purpose:** The variable set herb\_root\_effect\_on\_establishment creates a multiplier for the relative seed production rate based on the biomass of herbaceous roots, reflecting root crowding. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

50.0, 1., 300., 0.50, 100.0, 1., 500.0, 0.0, 150.0, 1., 600.0, 0.0

#### Sensitivity values:

(shrub upper x values changed only)

1 – 300

2 – 400

3 – 500

4 – 600

5 – 700

6 – 800

7 – 900

- ◆ Grass
- Savanna

- ◆ Trop. deciduous forest
- ◆ Temp. broad. ever. forest
- ◆ Temp. needle. ever. forest
- ◆ Temp. decid. forest
- ◆ Boreal decid. forest
- ◆ Mixed forest
- ◆ Tundra
- ◆ Polar

**Interpretation:** As elsewhere, changes to parameters affecting establishment had larger effects on facet cover than on nutrient modeling results, as expected. Annual evapotranspiration, soil temperature, plant available water, and decomposition coefficients were essentially unchanged. Annual net primary productivity changed only 20 g m<sup>-2</sup> (top) and live carbon density by up to 40 g m<sup>-2</sup>. Shrub cover changed up to 8% in response to herbaceous crowding of roots. Herbaceous roots changed up to 13%, in a pattern opposite to that of shrub change. Tree cover changed little.

**Conclusion:** The parameter is important to reflect the effect of competition for space by roots on facet cover.

### 39c. Herb root effect on establishment - Trees

**Purpose:** The variable set herb\_root\_effect\_on\_establishment creates a multiplier for the relative seed production rate based on the biomass of herbaceous roots, reflecting root crowding. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, but of a range and pattern similar to:

50.0, 1., 300., 0.50, 100.0, 1., 500.0, 0.0, 150.0, 1., 600.0, 0.0

#### Sensitivity values:

(tree upper x values changed only)

- 1 – 300
  - 2 – 400
  - 3 – 500
  - 4 – 600
  - 5 – 700
  - 6 – 800
  - 7 – 900
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. deciduous forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** Tree facet cover changed up to 8% in response to changes in establishment associated with herbaceous roots. Tree cover increased as the competition with herbaceous roots was reduced, as expected. Shrub cover changed little, but herbaceous cover changed up to 10% and bare ground cover up to 6.8%. Changes in other G-Range outputs assessed were small, such as the up to 80 g m<sup>-2</sup> increase in soil organic carbon and the 8 g m<sup>-2</sup> change in annual net primary productivity. Leaf area index changed less than 0.01, and live carbon density by up to 40 g m<sup>-2</sup>.

**Conclusion:** The parameter is important to reflect the effect of competition for space by roots on facet cover.

## 40a. Litter effect on establishment - Herbs

**Purpose:** The variable set `litter_effect_on_establish` creates a multiplier for the relative seed production rate based on the interference litter may have on seed establishment. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but of a range and pattern similar to:

300., 1., 1000., 0.1, 300., 1., 1000., 0.7, 300., 1., 1000., 0.7

### Sensitivity values:

(herb upper x values changed only)

- 1 – 700
  - 2 – 800
  - 3 – 900
  - 4 – 1000
  - 5 – 1100
  - 6 – 1200
  - 7 – 1300
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. deciduous forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** The changes to nutrients and productivity in association with changes in sensitivity to litter biomass were minor. Potential and annual evapotranspiration were essentially unchanged, as were plant available water and coefficients associated with decomposition. Annual net primary productivity changed by less than 20 g m<sup>-2</sup>, and live carbon density by less than 27 g m<sup>-2</sup> (top). Soil organic carbon changed up to 130 g m<sup>-2</sup>. Herbaceous facet cover changed in a regular manner, up to 27% (left). Shrub and tree cover were essentially unchanged.

**Conclusion:** The parameter is important to reflect the effect of heavy litter on seed establishment and on facet cover.

## 40b. Litter effect on establishment - Shrubs

**Purpose:** The variable set litter\_effect\_on\_establish creates a multiplier for the relative seed production rate based on the interference litter may have on seed establishment. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but of a range and pattern similar to:

300., 1., 1000., 0.1, 300., 1., 1000., 0.7, 300., 1., 1000., 0.7

### Sensitivity values:

(shrub upper x values changed only)

1 – 700

2 – 800

3 – 900

4 – 1000

5 – 1100

6 – 1200

7 – 1300

**Interpretation:** Only small changes in shrub cover were associated with changes in the effect litter had on establishment (left); it appears shrubs were rarely limited by litter. Herbs changed less than 2%, and trees were unchanged. Plant processes and production changed very little as well, such as the live carbon density shown (top) and soil organic carbon that changed up to just 4.2 g m<sup>-2</sup>.

**Conclusion:** The parameter is important to reflect the effect of heavy litter on seed establishment and on facet cover. In the current parameterization, however, the effect is very small.

## 40c. Litter effect on establishment - Trees

**Purpose:** The variable set litter\_effect\_on\_establish creates a multiplier for the relative seed production rate based on the interference litter may have on seed establishment. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but of a range and pattern similar to:

300., 1., 1000., 0.1, 300., 1., 1000., 0.7, 300., 1., 1000., 0.7

### Sensitivity values:

(shrub upper x values changed only)

- 1 – 700
  - 2 – 800
  - 3 – 900
  - 4 – 1000
  - 5 – 1100
  - 6 – 1200
  - 7 – 1300
- ◆ Grass
  - Savanna
  - Dense shrub
  - ▲ Open shrub
  - ◆ Desert
  - ◆ Trop. evergreen forest
  - ◆ Trop. deciduous forest
  - ◆ Temp. broad. ever. forest
  - ◆ Temp. needle. ever. forest
  - ◆ Temp. decid. forest
  - ◆ Boreal decid. forest
  - ◆ Mixed forest
  - ◆ Tundra
  - ◆ Polar

**Interpretation:** Like for the shrubs, tree cover was not really influenced by changes in sensitivity of establishment to sensitivity to litter. Tree cover changed less than 2% for the values tested (left), shrubs were essentially unchanged, and herbs changed less than 1%, except for temperature broadleaf evergreen forest, which declined 3% at the lowest sensitivities. Results from nutrient and productivity modeling were essentially unchanged, such as for soil organic carbon (above) and leaf area index (top).

**Conclusion:** The parameter is important to reflect the effect of heavy litter on seed establishment and on facet cover. In the current parameterization, however, the effect is very small.

## 41a. Woody cover effect on establishment - Herbs

**Purpose:** The variable set woody\_cover\_effect\_on\_establish creates a multiplier for the relative seed production rate based on the interference shading by woody plants may have on seed establishment. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but two examples cover most units:

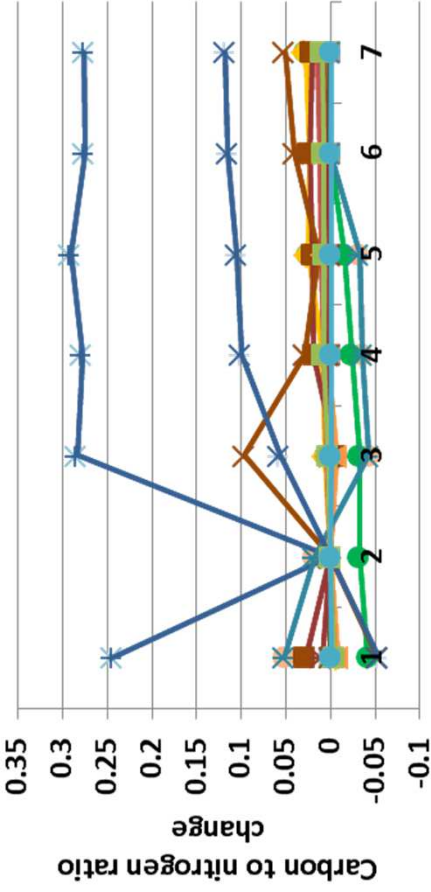

0.0, 1.0, 0.4, 0.0, 1.0, 0.5, 0.0, 0.0, 1.0, 0.35, 0.0  
 0.0, 1.0, 0.4, 0.0, 0.0, 1.0, 0.3, 0.0, 0.0, 1.0, 0.25, 0.0

### Sensitivity values:

(herb upper x values changed only)

- 1 – 0.35
- 2 – 0.40
- 3 – 0.45
- 4 – 0.50
- 5 – 0.55
- 6 – 0.60
- 7 – 0.65

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Trop. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in results in response to sensitivity to woody cover were small. Annual evapotranspiration changed less than 0.2 cm, and soil temperature and plant-available water were essentially unchanged. Soil organic carbon up to 310 g m<sup>-2</sup> (top), and carbon to nitrogen ratio changed up to 0.3. Live carbon density and annual net primary production each changed less than 35 g m<sup>-2</sup>, and leaf area index by 0.05. Herbaceous cover changed up to 24% (left), and shrubs and trees were essentially unchanged.

**Conclusion:** The parameter is important to reflect the effect of woody plants can have on vegetation in their understory.

## 41b. Woody cover effect on establishment - Shrubs

**Purpose:** The variable set woody\_cover\_effect\_on\_establish creates a multiplier for the relative seed production rate based on the interference shading by woody plants may have on seed establishment. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but two examples cover most units:

0.0, 1.0, 0.4, 0.0, 0.0, 1.0, 0.5, 0.0, 0.0, 1.0, 0.35, 0.0  
 0.0, 1.0, 0.4, 0.0, 0.0, 1.0, 0.3, 0.0, 0.0, 1.0, 0.25, 0.0

### Sensitivity values:

(shrub upper x values changed only)

1 – 0.25

2 – 0.30

3 – 0.35

4 – 0.40

5 – 0.45

6 – 0.50

7 – 0.55

**Interpretation:** Changes in nutrient and productivity results from G-Range were small when the effect of woody plants on establishment was changed. Responses such as annual and potential evapotranspiration, soil temperature, plant-available water, and decomposition coefficients were essentially unchanged. Net primary productivity changed up to 19 g m<sup>-2</sup> (top), and soil organic carbon by up to 120 g m<sup>-2</sup>. Shrub cover was sensitive, with changes up to 23% (left). Generally, the changes in shrubs were compensated by changes in herbs, with opposite change to shrubs of up to 25%.

**Conclusion:** The parameter is important to reflect the effect of woody plants can have on vegetation in their understory.

## 41c. Woody cover effect on establishment - Trees

**Purpose:** The variable set woody\_cover\_effect\_on\_establish creates a multiplier for the relative seed production rate based on the interference shading by woody plants. Two pairs of values define a linear regression for each facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, but two examples cover most units:

0.0, 1.0, 0.4, 0.0, 0.0, 1.0, 0.5, 0.0, 0.0, 1.0, 0.35, 0.0  
 0.0, 1.0, 0.4, 0.0, 0.0, 1.0, 0.3, 0.0, 0.0, 1.0, 0.25, 0.0

### Sensitivity values:

(tree upper x values changed only)

- 1 – 0.20
- 2 – 0.25
- 3 – 0.30
- 4 – 0.35
- 5 – 0.40
- 6 – 0.45
- 7 – 0.50

### Interpretation:

Changes in annual evapotranspiration, soil temperature, plant-available water, and decomposition coefficients were all small. Other responses showed small changes as well, such as leaf area index changing up to 0.037 (above), net primary production changing less than 12 g m<sup>-2</sup>, live carbon density changing up to 50 g m<sup>-2</sup>, and soil organic carbon changing less than 60 g m<sup>-2</sup>. Tree cover changed linearly with changes in sensitivity to woody cover (left), up to 21%. Shrubs changed up to 6%, and herbs changed in a fashion opposite to trees, up to 17% cover.

**Conclusion:** The parameter is important to reflect the effect of woody plants can have on vegetation in their understory.

## 42a. Nominal plant death rate - Herbs

**Purpose:** The variable set nominal\_plant\_death\_rate provides one value per facet, reflecting the baseline mortality rate of plants of that facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

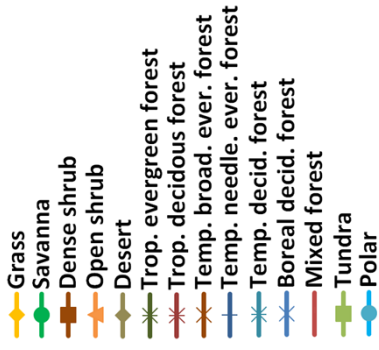

Various values, three examples suggest the range for units:

0.0065, 0.0002, 0.0002  
0.0020, 0.0009, 0.0002  
0.0072, 0.0012, 0.0010

### Sensitivity values:

(herbs only changed)

1 – 0.003  
2 – 0.004  
3 – 0.005  
4 – 0.006  
5 – 0.007  
6 – 0.008  
7 – 0.009

**Interpretation:** Results for nominal plant death rate are not available due to technical difficulties. Presumably G-Range is highly sensitivity to nominal plant death rates.

**Conclusion:** The parameter is critical to determining baseline mortality in plants.

## 42a. Nominal plant death rate - Shrubs

**Purpose:** The variable set nominal\_plant\_death\_rate provides one value per facet, reflecting the baseline mortality rate of plants of that facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, three examples suggest the range for units:

0.0065, 0.0002, 0.0002  
0.0020, 0.0009, 0.0002  
0.0072, 0.0012, 0.0010

### Sensitivity values:

(shrubs only changed)

1 – 0.0002  
2 – 0.0005  
3 – 0.0008  
4 – 0.0011  
5 – 0.0014  
6 – 0.0017  
7 – 0.0020

**Interpretation:** Results for nominal plant death rate are not available due to technical difficulties. Presumably G-Range is highly sensitivity to nominal plant death rates.

**Conclusion:** The parameter is critical to determining baseline mortality in plants.

## 42a. Nominal plant death rate - Trees

**Purpose:** The variable set nominal\_plant\_death\_rate provides one value per facet, reflecting the baseline mortality rate of plants of that facet.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various values, three examples suggest the range for units:

0.0065, 0.0002, 0.0002  
0.0020, 0.0009, 0.0002  
0.0072, 0.0012, 0.0010

### Sensitivity values:

(trees only changed)

1 – 0.0002  
2 – 0.0005  
3 – 0.0008  
4 – 0.0011  
5 – 0.0014  
6 – 0.0017  
7 – 0.0020

**Interpretation:** Results for nominal plant death rate are not available due to technical difficulties. Presumably G-Range is highly sensitivity to nominal plant death rates.

**Conclusion:** The parameter is critical to determining baseline mortality in plants.

### 43a. Water effect on death rate - Herbs

**Purpose:** The variable set `water_effect_on_death_rate` provides two sets of values per facet that define a linear regression. That regression is defined by the available water to potential evapotranspiration ratio and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

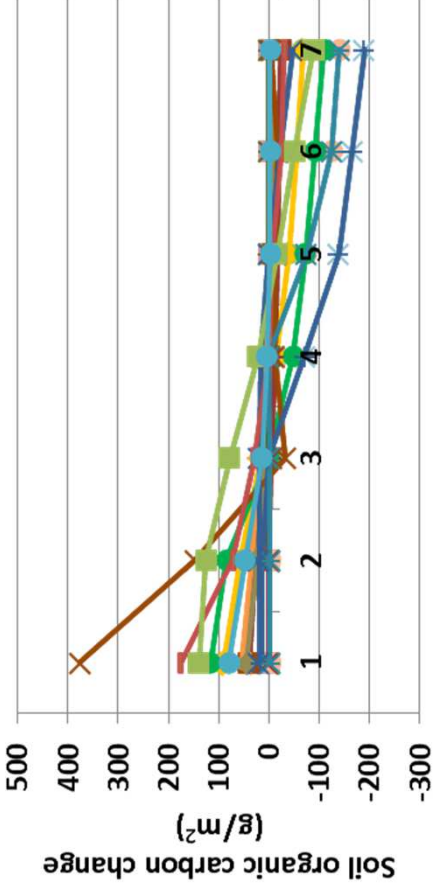

#### Baseline values

Various values, two examples suggest the nature of entries:  
 0.0, 0.08, 2.5, 0.0, 0.0, 0.0015, 2.0, 0.0, 0.0, 0.001, 2.0, 0.0  
 0.0, 0.10, 3.5, 0.0, 0.0, 0.0080, 2.5, 0.0, 0.0, 0.005, 2.5, 0.0

#### Sensitivity values:

(herbs lower y changed)

- 1 - 0.02
  - 2 - 0.04
  - 3 - 0.06
  - 4 - 0.08
  - 5 - 0.10
  - 6 - 0.12
  - 7 - 0.14
- Grass
  - Savanna
  - Dense shrub
  - Open shrub
  - Desert
  - Trop. evergreen forest
  - Trop. decid. forest
  - Temp. broad. ever. forest
  - Temp. needle. ever. forest
  - Temp. decid. forest
  - Boreal decid. forest
  - Mixed forest
  - Tundra
  - Polar

**Interpretation:** Annual evapotranspiration, plant-available soil water, soil temperature, and decomposition coefficients changed little in response to different sensitivity of herbs to water availability.

Modest changes were seen in other responses, such as soil organic carbon changing up to 380 g m<sup>-2</sup> (top), net primary productivity changed up to 23 g m<sup>-2</sup>, and live carbon density changed up to 30 g m<sup>-2</sup>. Herbaceous cover changed greatly with changes in sensitivity to water, up to 43% in most landscape units, and up to 88% in deserts (left). Shrub and tree facet cover changed little.

**Conclusion:** The parameter captures an important source of mortality for plants, water stress, and will be retained.

### 43b. Water effect on death rate - Shrubs

**Purpose:** The variable set water\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the available water to potential evapotranspiration ratio and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

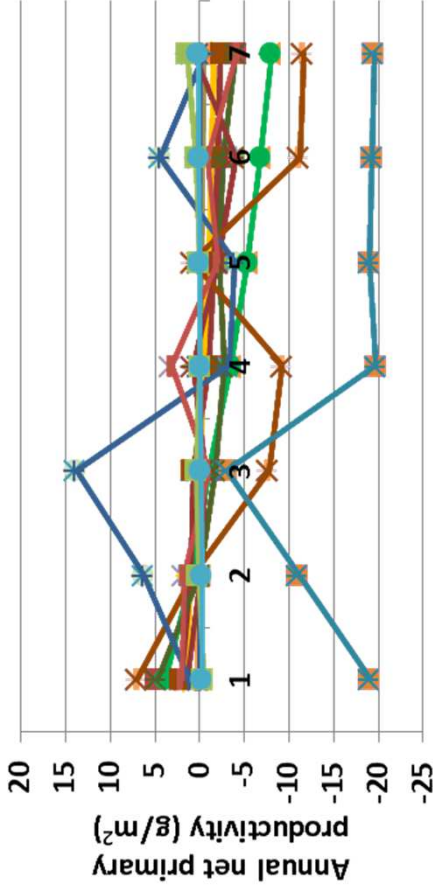

Various values, two examples suggest the nature of entries:  
 0.0, 0.08, 2.5, 0.0, 0.0, 0.0015, 2.0, 0.0, 0.0, 0.001, 2.0, 0.0  
 0.0, 0.10, 3.5, 0.0, 0.0, 0.0080, 2.5, 0.0, 0.0, 0.005, 2.5, 0.0

#### Sensitivity values:

(shrubs lower y changed)

- 1 – 0.000
- 2 – 0.002
- 3 – 0.004
- 4 – 0.006
- 5 – 0.008
- 6 – 0.010
- 7 – 0.012

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- \* Trop. evergreen forest
- \* Trop. deciduous forest
- \* Temp. broad. ever. forest
- \* Temp. needle. ever. forest
- \* Temp. decid. forest
- \* Boreal decid. forest
- \* Mixed forest
- \* Tundra
- \* Polar

**Interpretation:** Changes in annual net primary productivity were modest, up to 20 g m<sup>-2</sup> (top), and soil organic carbon changed up to 150 g m<sup>-2</sup> (above). Carbon to nitrogen ratio changed up to 0.34, and live carbon density by 41 g m<sup>-2</sup>. Leaf area index changed up to 0.057. Other changes in temperature and evapotranspiration were small. Shrub cover changes up to 24% in response to differences in sensitivity to water stress (left), and herbs change in an opposite pattern. Bare ground also changed up to 11%. Trees were essentially unchanged.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, water stress, and will be retained.

### 43c. Water effect on death rate - Trees

**Purpose:** The variable set water\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the available water to potential evapotranspiration ratio and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

#### Baseline values

Various values, two examples suggest the nature of entries:  
 0.0, 0.08, 2.5, 0.0, 0.0, 0.0015, 2.0, 0.0, 0.0, 0.0001, 2.0, 0.0  
 0.0, 0.10, 3.5, 0.0, 0.0, 0.0080, 2.5, 0.0, 0.0, 0.005, 2.5, 0.0

#### Sensitivity values:

(trees lower y changed)

- 1 - 0.000
- 2 - 0.002
- 3 - 0.004
- 4 - 0.006
- 5 - 0.008
- 6 - 0.010
- 7 - 0.012

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** As for most of the variables that primarily affect facet cover, the changes in productivity, nutrient modeling, etc. were small.

Evaporation, temperature, plant-available soil water and decomposition coefficients changed little. Leaf area index changed up to 0.066, and net primary productivity changed up to 22 g m<sup>-2</sup>. Live carbon density changed up to 100 g m<sup>-2</sup> (top) and soil organic carbon up to 82 g m<sup>-2</sup> (above). Changes in tree cover were up to 20% (left), and shrubs were unchanged, except for tropical deciduous forest, at 4.7%. Herbs changed opposite to trees, up to 29%.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, water stress, and will be retained.

## 44a. Grazing effect on death rate - Herbs

**Purpose:** The variable set grazing\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the grazing frequency and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 1.0, 0.06, 0.0, 0.0, 1.0, 0.003, 0.0, 0.0, 1.0, 0.003  
 0.0, 0.0, 1.0, 0.04, 0.0, 0.0, 1.0, 0.006, 0.0, 0.0, 1.0, 0.007

### Sensitivity values:

(herbs upper y value changed)

1 – 0.03

2 – 0.04

3 – 0.05

4 – 0.06

5 – 0.07

6 – 0.08

7 – 0.09

**Interpretation:** Changes in herbaceous facet cover were small, at 3.5%, in response to sensitivity to grazing frequency (left). Shrubs and trees were essentially unchanged, and bare ground therefore changed in opposition to herbs. As may be suspected from such small changes, the differences in other outputs from G-Range that were reported were quite small, such as live carbon density (top) and soil organic carbon (above), which changed less than  $13 \text{ g m}^{-2}$ .

**Conclusion:** The parameter captures a variety an important source of mortality for plants, grazing stress, and should be better quantified.

## 44b. Grazing effect on death rate - Shrubs

**Purpose:** The variable set grazing\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the grazing frequency and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 1.0, 0.06, 0.0, 0.0, 1.0, 0.003, 0.0, 0.0, 1.0, 0.003  
 0.0, 0.0, 1.0, 0.04, 0.0, 0.0, 1.0, 0.006, 0.0, 0.0, 1.0, 0.007

### Sensitivity values:

(shrubs upper y value changed)

1 – 0.0000

2 – 0.0015

3 – 0.0030

4 – 0.0045

5 – 0.0060

6 – 0.0075

7 – 0.0090

- ◆ Grass
- Savanna
- Dense shrub
- ▲ Open shrub
- ◆ Desert
- ✱ Trop. evergreen forest
- ✱ Trop. deciduous forest
- ✱ Temp. broad. ever. forest
- ✱ Temp. needle. ever. forest
- ✱ Boreal decid. forest
- ✱ Mixed forest
- Tundra
- Polar

**Interpretation:** Again, an effect on death rates, in this case grazing effect on shrub death, led to only small changes in G-Range output. Decomposition coefficients, plant-available water, soil temperature, and annual evapotranspiration changed little. Carbon to nitrogen ratio changed up to 0.19, and live carbon density changed up to 14.5 g m<sup>-2</sup>. Soil organic carbon changed up to 70 g m<sup>-2</sup> (above) and leaf area index changed by almost 0.02 (top). Shrub cover changed up to 2% (left), in response to sensitivity to grazing. Herbs changed up to 2.9% in a pattern opposite to shrubs. Trees were unchanged.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, grazing stress, and should be better quantified.

## 44c. Grazing effect on death rate - Trees

**Purpose:** The variable set grazing\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the grazing frequency and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 1.0, 0.06, 0.0, 0.0, 1.0, 0.003, 0.0, 0.0, 1.0, 0.003  
 0.0, 0.0, 1.0, 0.04, 0.0, 0.0, 1.0, 0.006, 0.0, 0.0, 1.0, 0.007

### Sensitivity values:

(trees upper y value changed)

1 – 0.0000

2 – 0.0015

3 – 0.0030

4 – 0.0045

5 – 0.0060

6 – 0.0075

7 – 0.0090

- ◆ Grass
- ◆ Savanna
- Dense shrub
- ▲ Open shrub

- \* Trop. evergreen forest
- \* Trop. deciduous forest
- \* Temp. broad. ever. forest
- \* Temp. needle. ever. forest
- \* Temp. decid. forest
- \* Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in nutrient concentrations and productivity, etc. were fairly small. Annual evapotranspiration changed up to 0.08 cm, and soil temperature and plant-available water were essentially unchanged. Soil organic carbon changed up to 67 g m<sup>-2</sup>, and live carbon density changed up to 23 g m<sup>-2</sup>. Carbon to nitrogen ratio changed up to 0.12 (top), and leaf area index changed up to 0.045 (above). Trees changed little in response to sensitivity in grazing, less than 2% (left). Shrubs were essentially unchanged. Herbs changed up to 3.2%, in a pattern generally opposite that of trees.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, grazing stress, and should be better quantified.

## 45a. Shading effect on death rate - Herbs

**Purpose:** The variable set shading\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the leaf area index and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 5.0, 0.06, 0.0, 0.0, 4.0, 0.003, 0.0, 0.0, 4.0, 0.003  
 0.0, 0.0, 5.0, 0.04, 0.0, 0.0, 4.0, 0.005, 0.0, 0.0, 4.0, 0.005

### Sensitivity values:

(herbs upper y value changed)

1 - 0.02

2 - 0.03

3 - 0.04

4 - 0.05

5 - 0.06

6 - 0.07

7 - 0.08

**Interpretation:** Changes in herbaceous death in response to shading caused significant changes to herb cover and smaller changes in other measures. Annual evapotranspiration changed up to 00.065. Soil temperature and plant-available water were essentially unchanged. Carbon to nitrogen ratio changed up to 0.27. Soil organic carbon (top) changed up to 463 g m<sup>-2</sup>, and net primary productivity changed up to 15 g m<sup>-2</sup>. Changes in herbaceous cover were relatively large, up to 34% (left). Shrubs and trees were unchanged, and so bare ground changed opposite to herbs.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, competition for light, and will be retained.

## 45b. Shading effect on death rate - Shrubs

**Purpose:** The variable set shading\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the leaf area index and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 5.0, 0.06, 0.0, 0.0, 4.0, 0.003, 0.0, 0.0, 4.0, 0.003  
 0.0, 0.0, 5.0, 0.04, 0.0, 0.0, 4.0, 0.005, 0.0, 0.0, 4.0, 0.005

### Sensitivity values:

(shrubs upper y value changed)

1 – 0.001

2 – 0.002

3 – 0.003

4 – 0.004

5 – 0.005

6 – 0.006

7 – 0.007

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in annual evapotranspiration were up to 0.042, and soil temperature and potential evapotranspiration were essentially unchanged. Decomposition coefficients did not change. Soil organic carbon changed up to 20 g m<sup>-2</sup>, and live carbon density changed up to 17 g m<sup>-2</sup> (top). Leaf area index changed up to 0.023, and net primary productivity by 14.5 g m<sup>-2</sup>. Shrub cover changed modestly under the values tested, up to 1.7% (left), and herb cover changed up to 2.1%. Tree facet cover was unchanged.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, competition for light, and will be retained.

## 45c. Shading effect on death rate - Trees

**Purpose:** The variable set shading\_effect\_on\_death\_rate provides two sets of values per facet that define a linear regression. That regression is defined by the leaf area index and its relation to plant death.

**Basis for assignment:** The values were inferred, then adjusted to improve model fit.

### Baseline values

Various but similar values; two examples are:

0.0, 0.0, 5.0, 0.06, 0.0, 0.0, 4.0, 0.003, 0.0, 0.0, 4.0, 0.003  
 0.0, 0.0, 5.0, 0.04, 0.0, 0.0, 4.0, 0.005, 0.0, 0.0, 4.0, 0.005

### Sensitivity values:

(trees upper y value changed)

- 1 - 0.001
- 2 - 0.002
- 3 - 0.003
- 4 - 0.004
- 5 - 0.005
- 6 - 0.006
- 7 - 0.007

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in soil organic carbon were small (top), with temperate boreal evergreen forest changing up to 51 g m<sup>-2</sup>. Annual net primary production changed up to 19 g m<sup>-2</sup>, and live carbon density changed up to 23 g m<sup>-2</sup>. Carbon to nitrogen ratio changed up to 0.083. Decomposition coefficients, plant-available soil water, and soil temperature was unchanged. Tree cover changed less than 2% (left), with tropical evergreen forest showing the largest change. Shrubs were essentially unchanged, and herbs changed up to 2.5%.

**Conclusion:** The parameter captures a variety an important source of mortality for plants, competition for light, and will be retained.

## 46a. Fall rate of standing dead - Herbs

**Purpose:** The variable `fall_rate_of_standing_dead` controls the rate at which dead vegetation falls to litter, with three values provided, one for each facet.

**Basis for assignment:** The values were initialized by the variable `FALR` within example applications of the Savanna model.

### Baseline values

0.10, 0.10, 0.10 for unit 1  
 0.12, 0.15, 0.15 for unit 2  
 0.02, 0.05, 0.05 for units 3 to 15

### Sensitivity values:

(herbaceous values changed)

- 1 – 0.005
- 2 – 0.015
- 3 – 0.025
- 4 – 0.035
- 5 – 0.045
- 6 – 0.055
- 7 – 0.065

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Leaf area index declined as the rate of standing dead increased (above), and soil organic carbon changed up to 364 g m<sup>-2</sup> (top). Primary production changed up to 69 g m<sup>-2</sup> in a pattern similar to leaf area index. Carbon to nitrogen ratio changed up to 0.32. Plant-available soil water changed up to 5.3 cm. Herbaceous cover changed up to 12% in response to differences in the fall rate of standing dead material (left). Shrubs changed up to 1.8%, in a general pattern similar to herbs, and trees changed up to 1%. Bare ground changed opposite to the other groups.

**Conclusion:** The parameter captures an ecosystem process known to be important, with standing dead providing extra forage for animals.

## 46b. Fall rate of standing dead - Shrubs

**Purpose:** The variable fall\_rate\_of\_standing\_dead controls the rate at which dead vegetation falls to litter, with three values provided, one for each facet.

**Basis for assignment:** The values were initialized by the variable FALR within example applications of the Savanna model.

### Baseline values

0.10, 0.10, 0.10 for unit 1

0.12, 0.15, 0.15 for unit 2

0.02, 0.05, 0.05 for units 3 to 15

### Sensitivity values:

(shrub values changed)

1 – 0.02

2 – 0.03

3 – 0.04

4 – 0.05

5 – 0.06

6 – 0.07

7 – 0.08

**Interpretation:** Annual evapotranspiration decreased up to 1.7 cm with low rates of standing dead fall in shrubs. Plant-available water changed up to 0.38 cm. Net primary productivity changed up to 45 g m<sup>-2</sup> (top), less so in non-tropical forest landscape units. Soil organic carbon changed in a manner similar to primary productivity, up to 239 g m<sup>-2</sup> for the tropical forests. Leaf area index changed less than 0.12 (above). Changes in the rate of fall of standing dead material from shrubs did not change shrub cover very much (< 0.5%), but herb cover did change up to 7% (left). Tree cover changed less than 1%.

**Conclusion:** The parameter captures an ecosystem process known to be important, with standing dead providing extra forage for animals.

## 46c. Fall rate of standing dead - Trees

**Purpose:** The variable `fall_rate_of_standing_dead` controls the rate at which dead vegetation falls to litter, with three values provided, one for each facet.

**Basis for assignment:** The values were initialized by the variable `FALR` within example applications of the Savanna model.

### Baseline values

0.10, 0.10, 0.10 for unit 1  
 0.12, 0.15, 0.15 for unit 2  
 0.02, 0.05, 0.05 for units 3 to 15

### Sensitivity values:

(tree values changed)

- 1 - 0.02
- 2 - 0.03
- 3 - 0.04
- 4 - 0.05
- 5 - 0.06
- 6 - 0.07
- 7 - 0.08

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Relatively large changes in G-Range output were seen. Responses shown above are included not because others were small, but because these responses are uncommon. Net primary production changed up to 27 g m<sup>-2</sup>, and soil organic carbon by 239 g m<sup>-2</sup>. Annual evapotranspiration changed up to 24 cm (top), and decomposition coefficients by 0.035 (above). Changes in the rate of standing dead fall from trees led to up to 1.1% change in tree facet cover, and similar magnitudes of change in shrubs. Herbaceous cover (left) showed complex changes up to 6.6%.

**Conclusion:** The parameter captures an ecosystem process known to be important, with standing dead providing extra forage for animals.

## 47. Death rate of deciduous leaves

**Purpose:** The variable `death_rate_of_deciduous_leaves` controls the rate of death of leaves following their senescence. The rate would presumably be set to approach all deciduous leaves dead by the time phenology is reset.

**Basis for assignment:** The value was inferred.

**Baseline values**  
0.40 in all units

**Sensitivity values:**

- 1 - 0.25
- 2 - 0.30
- 3 - 0.35
- 4 - 0.40
- 5 - 0.45
- 6 - 0.50
- 7 - 0.55

**Interpretation:** Plant-available soil water changed up to 2.2 cm, and decomposition coefficients up to 0.06. Annual evapotranspiration changed up to 55 cm (above). Soil organic carbon increased 142 g m<sup>-2</sup> in savannas under low leaf death rates. Live carbon density changed up to 278 g m<sup>-2</sup>, primary productivity up to 37.7 g m<sup>-2</sup>, and leaf area index by 0.67. Trees and shrub cover changed in a manner that was similar in pattern and magnitude (left), up to 6.1% for shrubs in the savanna landscape unit. Herb cover showed mixed responses, with changes up to 8.7%.

**Conclusion:** The parameter captures an ecosystem process of secondary importance, but helpful to show more realistic responses.

## 48. Drought deciduous

**Purpose:** The variable drought\_deciduous identifies the proportion of plants in a landscape unit and of a given facet type that are drought deciduous. A portion of leaves related to water availability and the death rate of deciduous leaves and this parameter is used to add incrementally to dead leaves.

**Basis for assignment:** The value was inferred, but required further research to assign better values.

### Baseline values

0.2, 0.2, 0.2 in all units

### Sensitivity values:

- 1 – 0.05, 0.05, 0.05
- 2 – 0.10, 0.10, 0.10
- 3 – 0.15, 0.15, 0.15
- 4 – 0.20, 0.20, 0.20
- 5 – 0.25, 0.25, 0.25
- 6 – 0.30, 0.30, 0.30
- 7 – 0.35, 0.35, 0.35

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Trop. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changed in G-Range output in response to changes in the proportion of plants that were drought deciduous were moderate. Plant-available water changed up to 0.28 cm (above), and annual evapotranspiration changed in an opposite manner, up to 4.3 cm. Soil organic carbon changed up to 115 g m<sup>-2</sup>, in the polar unit (top). Changes in facet cover were small in response to changes in proportions of drought deciduous plants. Trees changed less than 0.5%, and shrubs less than 0.8%. Herb cover changed up to 3.3%. These changed less to mixed patterns of change in bare ground left).

**Conclusion:** The parameter captures an ecosystem process of secondary importance, but it can be important in some ecosystems.

## 49. Fraction woody leaf nitrogen translocated

**Purpose:** The variable fraction\_woody\_leaf\_n\_translocated describes the proportion of leaf nitrogen that is translocated to other plant parts prior to the death of deciduous leaves. Woody plants have evolved to withdraw some nitrogen from leaves prior to their senescence.

**Basis for assignment:** The value was assigned based on the variable FORRTF in example files distributed with the Century model.

### Baseline values

0.3 in all units

### Sensitivity values:

- 1 - 0.15
- 2 - 0.20
- 3 - 0.25
- 4 - 0.30
- 5 - 0.35
- 6 - 0.40
- 7 - 0.45

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in evapotranspiration were small, up to 0.15 cm, and soil temperature, plant-available water, and decomposition coefficients were essentially unchanged. Soil organic carbon changed up to 90 g m<sup>-2</sup>, and the carbon to nitrogen ratio (the only metric tested directly associated with nitrogen) changed up to 0.315 (top). Annual net primary productivity changed up to 94 g m<sup>-2</sup> (above). Changing the fraction nitrogen translocated did not change facet cover very much, such as bare ground less than 2.3%, with herb cover changing opposite. Shrub and tree cover were unchanged.

**Conclusion:** The parameter captures an effect from an important adaptation in plants, and will be retained.

## 50a. Leaf death rate - Herbs

**Purpose:** The variable set leaf\_death\_rate provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

Various values were used, with example entries being:

0.035, 0.035, 0.035  
 0.036, 0.032, 0.032  
 0.068, 0.064, 0.065

### Sensitivity values:

(herb values only changed)

1 - 0.02  
 2 - 0.03  
 3 - 0.04  
 4 - 0.05  
 5 - 0.06  
 6 - 0.07  
 7 - 0.08

**Interpretation:** There were no changes in response to changes in herbaceous leaf death rate. The parameter was not incorporated in the herbaceous component of the model, and that is correct. The parameter is not used here. Instead, the variable set shoot\_death\_rate controls mortality.

**Conclusion:** The parameter is required to represent leaf death, and so will be retained. However, it will be made clear to users that the herbaceous value is not used.

## 50b. Leaf death rate - Shrubs

**Purpose:** The variable set leaf\_death\_rate provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

Various values were used, with example entries being:

0.035, 0.035, 0.035  
 0.036, 0.032, 0.032  
 0.068, 0.064, 0.065

### Sensitivity values:

(shrub values only changed)

- 1 - 0.02
- 2 - 0.03
- 3 - 0.04
- 4 - 0.05
- 5 - 0.06
- 6 - 0.07
- 7 - 0.08

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in annual evapotranspiration were up to 0.11 cm, and soil temperature just a fraction of degree. Soil organic carbon changed up to 80 g m<sup>-2</sup>, and carbon to nitrogen ratio changes up to 0.1. Net primary productivity changed little, less than 11 g m<sup>-2</sup>, and leaf area index 0.035 (top). Live carbon density changed almost 40 g m<sup>-2</sup>. Changes in facet cover were small, with bare ground changing up to 3.7%. Herbs changed in an opposite pattern, with shrubs and trees essentially unchanged.

**Conclusion:** The parameter is required to represent leaf death, and so will be retained.

## 50c. Leaf death rate - Trees

**Purpose:** The variable set leaf\_death\_rate provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

Various values were used, with example entries being:

0.035, 0.035, 0.035  
 0.036, 0.032, 0.032  
 0.068, 0.064, 0.065

### Sensitivity values:

(tree values only changed)

1 – 0.02  
 2 – 0.03  
 3 – 0.04  
 4 – 0.05  
 5 – 0.06  
 6 – 0.07  
 7 – 0.08

**Interpretation:** Changes in annual evapotranspiration were less than 20 cm, except for tropical evergreen forest, which increased up to 50 cm at high leaf death rates. Soil temperature changed up to 0.15 degree. Plant-available water changed up to 2.5 cm (above), and decomposition coefficients changed up to 0.026 in a pattern similar to live carbon density changes (top), which changed up to 130 g m<sup>-2</sup>. Net primary productivity changed up to 52 g m<sup>-2</sup>. Modest changes in facet cover occurred, such as a 1.5% change in trees (left), and a 2% change in shrubs and herbs.

**Conclusion:** The parameter is required to represent leaf death, and so will be retained.

## 51a. Fine root death rate - Herbs

**Purpose:** The variable set `fine_root_death_rate` provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The values were inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

Various values were used, with example entries being:

0.043, 0.043, 0.043  
 0.055, 0.054, 0.054  
 0.152, 0.149, 0.149

### Sensitivity values:

(herb values only changed)

1 – 0.05  
 2 – 0.07  
 3 – 0.09  
 4 – 0.11  
 5 – 0.13  
 6 – 0.15  
 7 – 0.17

**Interpretation:** Fine root death rate is not controlled by this variable in herbs. There was no change in any output associated with the change in sensitivity. This is correct. `Maximum_root_death_rate` influences fine root death rate in herbs.

**Conclusion:** The parameter is required to represent fine root death, and so will be retained. Users will be informed that the herbaceous parameter is not used.

## 51b. Fine root death rate - Shrubs

**Purpose:** The variable set `fine_root_death_rate` provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The values were inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

Various values were used, with example entries being:

0.043, 0.043, 0.043  
 0.055, 0.054, 0.054  
 0.152, 0.149, 0.149

### Sensitivity values:

(shrub values only changed)

- 1 - 0.05
- 2 - 0.07
- 3 - 0.09
- 4 - 0.11
- 5 - 0.13
- 6 - 0.15
- 7 - 0.17

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in fine root death rate in shrubs caused up to 0.26 cm in annual evapotranspiration. Soil temperature, plant-available soil water, and decomposition coefficients were essentially unchanged. Soil organic carbon changed up to 185 g m<sup>-2</sup>, and annual net primary production changed up to 20 g m<sup>-2</sup>. Live carbon density changed up to 1600 g m<sup>-2</sup> (top), and carbon to nitrogen ratio up to 0.33. Herbaceous cover mostly declined, up to 4% (left), and shrubs and tree facet cover were essentially unchanged.

**Conclusion:** The parameter is required to represent fine root death, and so will be retained.

### 51c. Fine root death rate - Trees

**Purpose:** The variable set `fine_root_death_rate` provides one value per facet that quantifies leaf death rate per month.

**Basis for assignment:** The values were inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

#### Baseline values

Various values were used, with example entries being:

- 0.043, 0.043, 0.043
- 0.055, 0.054, 0.054
- 0.152, 0.149, 0.149

#### Sensitivity values:

(tree values only changed)

- 1 – 0.05
- 2 – 0.07
- 3 – 0.09
- 4 – 0.11
- 5 – 0.13
- 6 – 0.15
- 7 – 0.17

**Interpretation:** Changes were small or showed no difference in annual evapotranspiration, soil temperature, plant-available water, and decomposition coefficients. Soil organic carbon changed up to 173 g m<sup>-2</sup>, and live carbon density up to 1549 g m<sup>-2</sup> (top). Carbon to nitrogen ratio changed up to 0.31, and net primary productivity changed little, less than 20 g m<sup>-2</sup>. Leaf area index changed up to 0.048. Herbaceous cover changed up to 4% when fine root death rate in trees was changed, and shrub and tree facet cover were essentially unchanged.

**Conclusion:** The parameter is required to represent fine root death, and so will be retained.

## 52a. Fine branch death rate - Shrubs

**Purpose:** The variable set `fine_branch_death_rate` provides one value per facet that quantifies leaf death rate per month. A placeholder is used for herbs, but they have no fine branches, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

0.0, 0.008, 0.008

### Sensitivity values:

(shrubs values only changed)

1 – 0.002

2 – 0.004

3 – 0.006

4 – 0.008

5 – 0.010

6 – 0.012

7 – 0.014

**Interpretation:** Changes with fine branch death rate differences included a 0.63 cm change in annual evapotranspiration, and small changes in soil temperature and plant-available water. Soil organic carbon changed up to 127 g m<sup>-2</sup> (above), and live carbon density declined 193 g m<sup>-2</sup> in tropical evergreen forest. Annual net primary productivity changed up to 29 g m<sup>-2</sup>, and leaf area index up to 0.07. Herbaceous cover changed up to 7.3% in response to changes in fine branch death rate in shrubs (left), and shrub and trees were essentially unchanged; bare ground changed opposite herbs.

**Conclusion:** The parameter is required to represent fine branch death, and so will be retained.

## 52b. Fine branch death rate - Trees

**Purpose:** The variable set `fine_branch_death_rate` provides one value per facet that quantifies leaf death rate per month. A placeholder is used for herbs, but they have no fine branches, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

### Baseline values

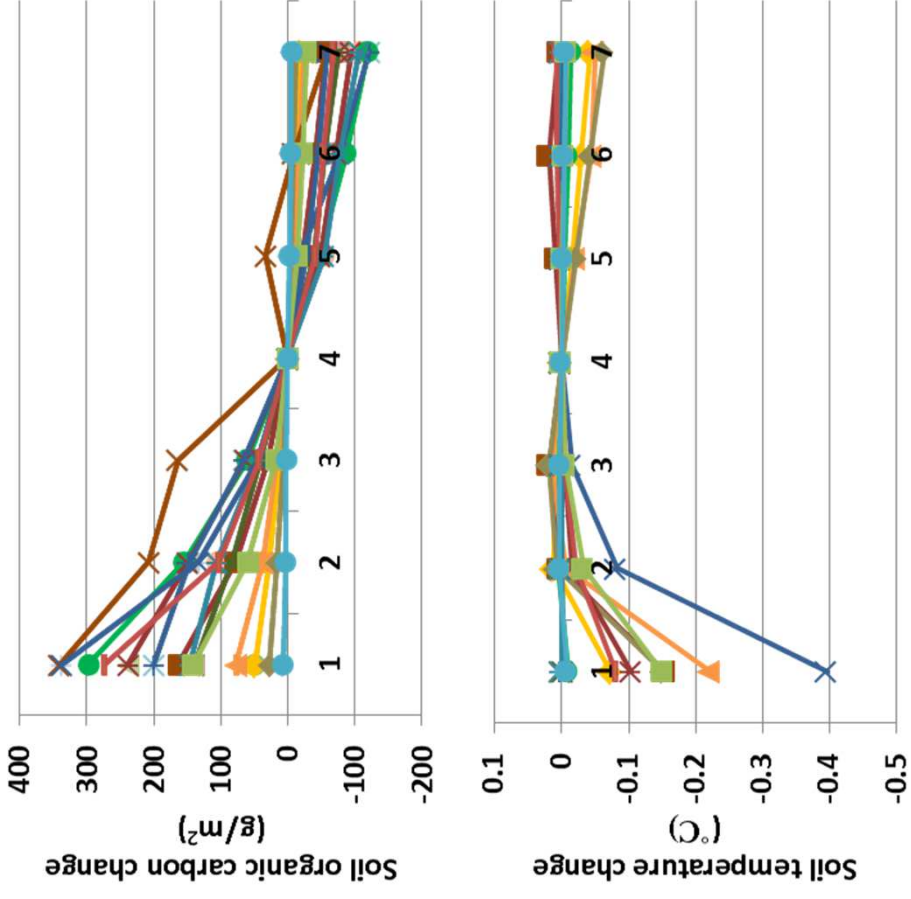

0.0, 0.008, 0.008

### Sensitivity values:

(shrubs values only changed)

- 1 - 0.002
- 2 - 0.004
- 3 - 0.006
- 4 - 0.008
- 5 - 0.010
- 6 - 0.012
- 7 - 0.014

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Annual evapotranspiration changed, mostly increased, up to 11.8 cm at low levels of fine branch death rates. Soil temperature decreased by almost 0.4 degrees (above). Decomposition coefficients changed up to 0.015. Soil organic carbon changed up to 336 g m<sup>-2</sup> (top), and carbon to nitrogen ratio changed up to 1.5, in a pattern similar to soil organic carbon. Annual net primary productivity changed up to 42.2 g m<sup>-2</sup>, and leaf area index by 0.14. Herbaceous cover changed up to 14% with changes to the fine branch death rate in trees. Shrubs and trees changed little.

**Conclusion:** The parameter is required to represent fine branch death, and so will be retained.

### 53a. Coarse branch death rate - Shrubs

**Purpose:** The variable set coarse\_branch\_death\_rate provides one value per facet that quantifies coarse branch death rate per month. A placeholder is used for herbs, but they have no coarse branches, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

#### Baseline values

Various values, but most are like:

0.0, 0.004, 0.004  
0.0, 0.005, 0.005

#### Sensitivity values:

(shrubs values only changed)

- 1 – 0.002
- 2 – 0.003
- 3 – 0.004
- 4 – 0.005
- 5 – 0.006
- 6 – 0.007
- 7 – 0.008

**Interpretation:** Changes with coarse branch death rate caused only small changes in responses. Annual evapotranspiration changed less than 0.15 cm, and plant-available water less than 0.03 cm. Soil organic carbon changed up to 72 g m<sup>-2</sup> (above), and annual net primary productivity changed less than 20 g m<sup>-2</sup>. Live carbon density changed up to 35 g m<sup>-2</sup>. In relation to changes in coarse branch death rate, herbaceous cover changed up to 4% (left), and shrubs and trees changed very little.

**Conclusion:** The parameter is required to represent coarse branch death, and so will be retained.

### 53b. Coarse branch death rate - Trees

**Purpose:** The variable set coarse\_branch\_death\_rate provides one value per facet that quantifies coarse branch death rate per month. A placeholder is used for herbs, but they have no coarse branches, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by similar variables in example Savanna applications. Values were adjusted to improve model fit.

#### Baseline values

Various values, but most are like:

- 0.0, 0.004, 0.004
- 0.0, 0.007, 0.007

#### Sensitivity values:

(shrubs values only changed)

- 1 - 0.002
- 2 - 0.003
- 3 - 0.004
- 4 - 0.005
- 5 - 0.006
- 6 - 0.007
- 7 - 0.008

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes annual evapotranspiration and soil temperature were small, and decomposition coefficients were essentially unchanged. Changes in soil organic carbon (above) were mostly small, except for temperate broadleaf evergreen forest. Carbon to nitrogen ratio changed up to 0.22(top). Annual net primary productivity changed up to 22.3 g m<sup>-2</sup>. Changes in coarse branch death rates caused small changes in herbaceous facet cover (left), up to 4%. Shrub and tree cover changed very little, and as expected, bare ground cover changed in a pattern opposite to herbs.

**Conclusion:** The parameter is required to represent coarse branch death, and so will be retained.

## 54a. Coarse root death rate - Shrubs

**Purpose:** The variable set coarse\_root\_death\_rate provides one value per facet that quantifies coarse root death rate per month. A placeholder is used for herbs, but they have no coarse roots, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by variables in example Savanna applications, then adjusted.

### Baseline values

Various values, but most are like:

0.0, 0.006, 0.005  
0.0, 0.008, 0.008

### Sensitivity values:

(shrubs values only changed)

- 1 - 0.004
- 2 - 0.005
- 3 - 0.006
- 4 - 0.007
- 5 - 0.008
- 6 - 0.009
- 7 - 0.010

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. deciduous forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes with secondary responses such as evapotranspiration, soil temperature, plant-available water, and decomposition coefficients were small. Annual net primary productivity changed up to 18 g m<sup>-2</sup>, and leaf area index by less than 0.06. Soil organic carbon changed up to 58 g m<sup>-2</sup> (above), and live carbon density changed up to 1356 g m<sup>-2</sup>. Carbon to nitrogen ratios changed up to 0.1. Changes in coarse root death rates led to up to 3.3% changes in herbaceous facet cover (left), and very small changes in shrub and tree cover.

**Conclusion:** The parameter is required to represent coarse root death, and so will be retained.

## 54b. Coarse root death rate - Trees

**Purpose:** The variable set coarse\_root\_death\_rate provides one value per facet that quantifies coarse root death rate per month. A placeholder is used for herbs, but they have no coarse roots, and so that value is not used.

**Basis for assignment:** The value was inferred, but informed by variables in example Savanna applications, then adjusted.

### Baseline values

Various values, but most are like:

0.0, 0.006, 0.005  
0.0, 0.008, 0.008

### Sensitivity values:

(tree values only changed)

- 1 - 0.004
- 2 - 0.005
- 3 - 0.006
- 4 - 0.007
- 5 - 0.008
- 6 - 0.009
- 7 - 0.010

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Live carbon density was the only large-scale change in response to differences in coarse root death rate (top), with changes up to 1000 g m<sup>-2</sup>. Leaf area index changed up to 0.05 (above). Annual net primary productivity changed up to 16 g m<sup>-2</sup>, and carbon to nitrogen ratio changed up to 0.26. Other variables such as soil temperature and plant-available water changed little. None of the facet covers changed notably in response to changes in coarse root death rate, do the degree that bare ground cover changed less than 1% (left).

**Conclusion:** The parameter is required to represent coarse root death, and so will be retained.

## 55. Fraction carbon grazed returned

**Purpose:** The variable set `fraction_carbon_grazed_returned` describes the portion of carbon that is grazed that is returned to the system as feces.

**Basis for assignment:** The value was assigned based on GRET/GFCRET, which is part of the example files distributed with the Century model.

**Baseline values**  
0.3 for all units

**Sensitivity values:**

- 1 – 0.15
  - 2 – 0.20
  - 3 – 0.25
  - 4 – 0.30
  - 5 – 0.35
  - 6 – 0.40
  - 7 – 0.45
- 
- The legend consists of 14 items, each with a colored symbol and a corresponding ecosystem name: Grass (yellow diamond), Savanna (green circle), Dense shrub (brown square), Open shrub (orange triangle), Desert (olive diamond), Trop. evergreen forest (green asterisk), Trop. deciduous forest (red asterisk), Temp. broad. ever. forest (orange asterisk), Temp. needle. ever. forest (blue asterisk), Temp. decid. forest (light blue asterisk), Boreal decid. forest (red asterisk), Mixed forest (green square), Tundra (blue square), and Polar (blue circle).

**Interpretation:** Results for the fraction carbon grazed returned are not available due to technical difficulties. We suspect that changes in the fraction of carbon that is returned would yield relatively small changes to model output.

**Conclusion:** The parameter captures a known component of ecosystem processes, the return of carbon to the system from herbivores.

## 56. Fraction excreted nitrogen in feces

**Purpose:** The variable `fraction_excreted_n_to_feces` defines the fraction of nitrogen that is in feces. The remainder is in urine and may be volatilized.

**Basis for assignment:** The value was assigned based on the variable `FACESFR` in example applications of the Savanna model.

**Baseline values**  
0.5 for all units

**Sensitivity values:**

- 1 – 0.35
- 2 – 0.40
- 3 – 0.45
- 4 – 0.50
- 5 – 0.55
- 6 – 0.60
- 7 – 0.65

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. ever. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in secondary results from G-Range, such as annual evapotranspiration, plant-available water, decomposition coefficients, and soil temperature, were very small. Carbon to nitrogen ratio changed up to 0.29 (top), and soil organic carbon changed up to 75 g m<sup>-2</sup> (above). Live carbon density changed 49 g m<sup>-2</sup>, and annual net primary productivity less than 20 g m<sup>-2</sup>. Changes in the fraction of excreted nitrogen in feces caused small changes, up to 4%, in herbaceous facet cover (left). Shrubs and trees were essentially unchanged.

**Conclusion:** The parameter represents an important relationship in ecosystems with large herbivores, and will be retained.

## 57. Fraction grazed by facet

**Purpose:** The variable `fraction_grazed_by_facet` defines the distribution of grazing across the different facets. The values should sum to 1.

**Basis for assignment:** The values were inferred based upon typical diets of livestock.

### Baseline values

0.8, 0.25, 0.10 for unit 1 (which is incorrect, it should sum to 1)  
 0.8, 0.15, 0.05 for units 2 to 15

### Sensitivity values:

- 1 – 0.65, 0.27, 0.08
- 2 – 0.70, 0.23, 0.07
- 3 – 0.75, 0.19, 0.06
- 4 – 0.80, 0.15, 0.05
- 5 – 0.85, 0.11, 0.04
- 6 – 0.90, 0.07, 0.03
- 7 – 0.95, 0.03, 0.02

**Interpretation:** Changes in secondary responses from G-Range, such as decomposition coefficients, plant-available water, soil water, and annual evapotranspiration were small. Soil organic carbon changed up to 96 g m<sup>-2</sup>, and carbon to nitrogen ratio changed up to 0.15. Live carbon density changed up to 100 g m<sup>-2</sup>, in a pattern similar to the responses shown. Changes to the fraction grazed by facet changed herbaceous facet cover but up to 8%, and may be in a direction opposite than expected. Shrub and tree cover changed little.

**Conclusion:** The distribution of grazing must be defined, given the logic of the model. More careful assignment of the values would be helpful.

## 58. Fraction grazed

**Purpose:** The variable fraction\_grazed defines the annual proportion of plant material that is grazed.

**Basis for assignment:** The value was assigned based on FLGREM, which is a component in the example files distributed with the Century model, but also in line with typical offtake values for livestock.

**Baseline values**  
0.35 for all units

**Sensitivity values:**

- 1 – 0.20
- 2 – 0.25
- 3 – 0.30
- 4 – 0.35
- 5 – 0.40
- 6 – 0.45
- 7 – 0.50

- Grass
- Savanna
- Dense shrub
- Open shrub
- Desert
- Trop. evergreen forest
- Trop. decid. forest
- Temp. broad. ever. forest
- Temp. needle. ever. forest
- Temp. decid. forest
- Boreal decid. forest
- Mixed forest
- Tundra
- Polar

**Interpretation:** Changes in the fraction of productivity grazed were significant, such as for annual evapotranspiration (above). Soil temperature changed up to one degree in a direction opposite to evapotranspiration. Annual net primary productivity changed up to 33 g m<sup>-2</sup>. It appears compensatory vegetation production is occurring. Live carbon density changed up to 340 g m<sup>-2</sup>, and leaf area index changed up to 0.42. Herbaceous facet cover changed up to 14% in response to changed fraction grazed, in a pattern that may be opposite than expected. Shrubs and trees changed little.

**Conclusion:** The proportion offtake by livestock or wildlife is a critical variable defined for examples, and must be retained.

## Future Steps

This sensitivity analysis is part of a joint approach to assessing G-Range. Here extensive tests were conducted in a *spatial* way, but for a single year. Complementary analyses by Dr. Sircely are using specific sites where field data provide an ability to make detailed comparisons through *time*. With results of from these sensitivities and the site-specific analyses to refer to, we are well placed to adjust the G-Range application. Specifically, we will:

- Correct coding errors that have been identified by the results of sensitivity analyses. No changes were made to the G-Range model coding during these analyses, so as to preserve a single baseline for comparison;
- Incorporate a fire frequency spatial surface into the application, and edit fire parameters;
- Rebalance and parameterize the G-Range application given what has been learned, jointly (to the degree possible) minimizing deviations from the spatial surfaces and site-specific observations.

We will then release the model to be used by others, train users, and continue in our own work to address research questions and improve G-Range.

## Acknowledgement

Our thanks to Dr. Philip Thornton and the International Livestock Research Institute for providing financial support for sensitivity analyses of G-Range. Our continued thanks to the developers of Century, which forms a foundation for G-Range.

**Appendix B.** The FIT.AML Arc Macro Language program. The program was used to run a G-Range simulation and create spreadsheets reporting the goodness of fit between observed data layers and the simulated responses. (Note that some lines wrap here, but not in the file itself.)

```

/* An AML that runs G-RANGE, exports selected projects, and compares those to selected existing layers.
/* The goal is for the results to be 15 lines (one per land unit) summarizing the fit of the model and
/* the existing layers.
/*
/* NOTE that all ASC files exported and the working workspace are deleted
/*
/* At 0.5 degree resolution, there are at least 81 cells in each of the biomes.
/* Specifically, zone 3 has 81, zones 4 and 5 have 97, zone 7 has 107, and the remainder have several
/* hundred or more. So all the fits matter.
/*
/*
/* February 2, 2013 - Changing the percent error estimates
/* February 9, 2013 - A division on the error is still being calculated. I don't want that. Changing.
/* March 29, 2013 - An error in LAI calculations, using just the herbaceous layers. Repaired.
/* May 14, 2013 - Edited to include the other fitting procedure, the one that calculates FACETS.
/*
/* Now the model runs once, but the two reports are generated.
